of which the following is an abstract The experiments which they had made in studying the effects of climate in the evolution of tuberculosis inoculated in the pleura of the guinea pig had taught them that this influence was inconsiderable and had not the importance which medical prognosis had been wont to attach to it They had enabled them in addition, to observe remarkable differences in the progress of the disease and in the nature of the lesions in various animals of the same species which had been similarly inoculated and submitted to the same conditions of climate and food Certain of these animals offered such a remarkable resistance that it would seem that in their cases the infection had not matured or had been spontaneously cured, some even increased in weight and the records showed that some died quite fat whilst at the same time exhibiting lesions of generalised tuberculosis In nearly half the number of cases the lesions remained localised in the thorax Affections of the serous membranes the pleura pericardium and peritoneum were extremely frequent and exhibited the whole series of tuberculous lesions of such membranes met with in man—dry sero-fibrinous, purulent and hæmorrhagic forms A very special feature of tuberculosis in guinea pigs, of which they had met with six examples was rupture of the spleen with profuse hæmorrhage into the peritoneum The spleen was often affected to such an extent that they had seen it weigh more than one tenth of the animal Most of the lesions met with having their counterpart in human pathology they could compare these experimental results with what was found in tuberculous human beings It was therefore internal causes which together constituted the "soil" far more than external causes and climatic influences which determined the nature of the lesions and general progress of the disease The chances of tuberculous infection were almost the same for a large number of human subjects, the onset was also very similar, but the progress of the disease was very different in individuals If the number of men who resisted it was relatively considerable and larger than was the case with their guinea pigs it was because man was less liable to tuberculosis than the guinea-pig, and he was slowly infected and in small doses, and not in wholesale doses, as in their experimental inoculations

Dr AMREIN (Arosa) then read an interesting paper upon

The Physiological Principles of High Altitude Treatment and their Importance in Tuberculosis

He presented the following table of comparison of the results of different climates —

THE RESULTS OF DIFFERENT CLIMATES COMPARED

—	No of patients	Average length of residence	First stage	Second and third stages	Bilateral affection	Results: General: Improved	Results: General: Stationary	Results: General: Worse (including deaths)	Results: Local: Arrest	Results: Local: Improved (including arrest)	Results: Local: Stationary	Results: Local: Worse
		Months	Per cent	Per cent	Per cent	Per cent	Per cent	Per cent	Per cent	Per cent	Per cent	Per cent

Dr P S HICHENS (Rossclare) read a paper entitled

A Query as to whether any Special Types of Pulmonary Tuberculosis and its Complications are Unsuitable for Treatment in the Climate of the British Isles

He remarked that they had heard very much hitherto about the successes of the sanatorium treatment but very little about its failures According to some writers, it might be imagined that there were no failures, but yet, even excluding the most advanced cases and the cases in which acute miliary generalisation and violent hæmorrhages intervened there were undoubtedly cases the rate of progress of which was at any rate a considerable disappointment Were these disappointing cases of any special type of the disease or its complications? So far as his own small experience had gone he had had types of disease the rate of progress of which had been a disappointment to him. In one type the disease had assumed a bronchitic form, in the others the disease of the lungs, in whatever form, was associated with persistent diarrhœa and very irregular pyrexia Two cases illustrating these types of disease were described These cases had improved but very slowly and not [illegible] forms of disease which might [illegible] much more serious With the exc[illegible] monia and cases associated with [illegible] most of the ordinary forms of tuberculous disease of the lungs and its complications under his care The ordinary rapidly spreading broncho pneumonic forms and chronic forms with excavation and associated with severe tuberculous laryngitis and tuberculous peritonitis had all done extremely well He thought that it would be of great interest to know whether others had had the same experience in other types of disease in whose progress they had been disappointed. Would these types do better in a more perfect climate or would their progress be disappointing under any circumstances? The excellent results obtained by the sanatorium treatment of consumption in the British Isles were now known to all and he thought our knowledge would now be better advanced by discussing our failures than by boasting about our successes

Dr THEM ZAMMIT (Malta) communicated a paper on

Tuberculosis in the Maltese Islands

He said that the mortality from tubercle in Malta was exceptionally low As the general death rate was not very low, and as overcrowding and the other debilitating agencies were by no means rare the comparative freedom from tubercle must be due to the sum total of telluric and atmospheric conditions which constituted climate It was a well known fact in the island that tuberculous diseases in the cattle and among the domestic animals were of rare occurrence The percentage of deaths from tubercle in relation to the general death-rate was as follows: During 1890, 9·2; during 1891, 9·3; during 1892, 8·9; during 1893, 9·2; during 1894, 6·3; during 1895, 6·8; during 1896, 8·6; during 1897, 8·1; during 1898, 10·7; and during 1899, 9·4—the average being 8·65 for 10 years. Comparing this with the proportion of deaths from tubercle to the general mortality of other countries they found that Malta stood at the bottom of the list. Detailed tables gathered from the official reports of the Public Health Department of Malta were given to demonstrate the fact.

Dr. TH. STEPHANI (Beauregard, Montana, Valais) communicated a paper on

Statistics and Results of the High Altitude Treatment in Pulmonary Tuberculosis.

He said that from observation of 150 tuberculous patients treated at Montana from 1897 to 1900 the following statistics were obtained:—1. Form of the disease: dry infiltrations, 34 per cent.; bronchial types, 30 per cent.; cases with cavitation, 17 per cent.; congestive forms, 13 per cent.; pleuritic cases, 3 per cent.; abdominal forms, 2 per cent.; and tuberculous adenitis, 1 per cent. The pulmonary lesions were more frequently bilateral (53 per cent.) and were more frequently situated on the right (27 per cent.) than on the left (20 per cent.). Laryngeal complications ranked in the proportion of 15 per cent. Heredity was present less frequently (44 per cent.) than it was absent (56 per cent.). The bacillus of Koch was present in three-quarters of the cases, or in almost all those in which it was possible to collect the expectoration. The transmission of tuberculosis from man to man was obvious in 80 per cent. of the cases—a fact which proved the significance of contagion. The inquiry made on this matter showed how many barracks, convents, and business offices were common foci for the propagation of tuberculosis. The part played by the pleura as a starting-point of the disease was sufficiently striking, for in 14 per cent. of the cases pulmonary tuberculosis commenced with a pleurisy, and in 18 per cent. injuries to the pleura were found to be described as having taken place several years previously to the development of the phthisis. 2. As regarded appetite, there was a decided improvement in 97 per cent. of the cases, which showed itself in 67 per cent. by a progressive rise in weight. 3. Extension of thoracic capacity, due above all to rarefaction of the air, was frequently noted. 4. The cardiac troubles ascribed to high altitudes had only been noticed in one out of the 150 cases; it was a case of congestive tuberculosis, with malformation of the heart that had already been diagnosed when in the plain. 5. Nervous affections had not been observed. 6. Hæmoptyses did not appear to be any more frequent at high altitudes than on the level, since 35 per cent. had manifested them when at home, and not at the sanatorium, while only 1½ per cent. of the patients had hæmoptysis for the first time at the sanatorium. 7. Fever was often combated most effectually by the Alpine climate—it had yielded, in fact, in 60 per cent. of the cases. 8. As to the results from the point of view of actual recovery, high altitude treatment gave the following figures: 12 per cent. completely cured; 50 per cent. improved and half cured; 20 per cent. with condition stationary; and 18 per cent. with condition worse, or with fatal issue. The 12 per cent. of cures might be subdivided thus: febrile cases with cavities and laryngitis 0·7 per cent., or 4 per cent. of cavities; congestive cases without fever 0·7 per cent., or 5 per cent. of congestive cases; bronchitic cases with fever 0·7 per cent., and bronchitic cases without fever 1·3 per cent. (2 per cent., or 7 per cent. of bronchitic cases); cases of dry infiltration—febrile with laryngitis 0·7 per cent., afebrile with laryngitis 0·7 per cent., and afebrile without laryngitis 0·7 per cent. (8·4 per cent., or 24 per cent. cases of dry infiltration); pleuritic afebrile cases 0·7 per cent., or 25 per cent. of pleuritic subjects; and cases of abdominal tuberculosis 0·7 per cent., or 33 per cent. of cases of abdominal tuberculosis. It was therefore the cases of dry infiltration (a group which embraced three-fourths of the incipient cases of tuberculosis) that furnished the most hopeful percentage of recovery. Afebrile forms were more favourable than were the febrile. Laryngeal complications, although troublesome, did not render cure impossible. Two-thirds of the cured cases were free from hereditary taint, which went to prove that the non-hereditary cases had a better chance of recovery. Dr. Stephani arrived at the following conclusions:—1. The high altitude treatment was indicated in all forms of tuberculosis. 2. The treatment yielded on an average 12 per cent. of complete cures, 50 per cent. of improvements, 20 per cent. of cases in which the tuberculous process was arrested, and 18 per cent. of failures. 3. The more a case conformed to the type of an incipient tuberculosis of the pleuritic or dry form, free from pyrexia or other complication and devoid of hereditary taint, the greater was the chance of recovery. 4 The treatment was only contra-indicated in cases of the asthmatic or congestive type accompanied by cardiac disease.

A paper by Dr. P. JONNART and Dr. GUETSCHEL was then read embodying the Results of the High-altitude Cure at the Sanitorium d'Hauteville, Ain, France, in which by statistics of results obtained at the sanatorium after nine months' working they arrived at the indications and contra-indications of the high-altitude cure.

WEDNESDAY, JULY 24TH.

The proceedings of the section were opened on Wednesday morning by Dr. G. A. HERON (London) who started a discussion upon

The Therapeutic and Diagnostic Value of Tuberculin in Human Tuberculosis.

Dr. HERON said that it had been laid down that the curative possibilities of tuberculin were confined to comparatively early stages of the disease. His belief was that tuberculin would be regarded as one of the most remarkable of the discoveries given to mankind by Professor Koch.

Professor R. KOCH (Berlin) said that tuberculin had a diagnostic and a therapeutic value. A single injection was sufficient to give a correct diagnosis in 97 to 98 per cent. of cattle. In the human subject it was very valuable and without danger if properly injected. When the first injection gave a faint reaction a second injection of the same quantity frequently, or indeed generally, gave a very marked reaction. From the study of over 3000 cases he had come to the conclusion that as a diagnostic test tuberculin was almost absolute. It was very valuable in cases of apical pneumonia, especially when influenza was suspected, and also in cases of pleurisy. In early uncomplicated cases it was of great value when used therapeutically and a complete cure frequently followed. To obtain the full value the temperature should be normal before the injections were begun.

Sir RICHARD DOUGLAS POWELL (London) pointed out that in the cases of mixed infection Professor Koch admitted that tuberculin was not very advantageous.

Professor W. OSLER (Baltimore) said that in the Johns Hopkins Hospital tuberculin was used as a routine diagnostic method. Tuberculin was harmless, but as a therapeutic agent it must have a limited value.

Dr. B. FRAENKEL (Berlin) pointed out that the danger of tuberculin was that the doses given were too large and increased at too short intervals, but when these errors were avoided the results were beneficial.

Dr. DENYS (Louvain) found that the injection of tuberculin subsequently to that of tubercle bacilli exercised a delaying influence; without tuberculin the animals died with disseminated tuberculosis.

Dr. CHARLES DENISON (Denver) read a paper on the Uses of Tuberculin.

Dr. C. THEODORE WILLIAMS (London) dissented from the view that tuberculin was harmless. At the Brompton Hospital for Diseases of the Chest his experience was that tuberculin in cases of early phthisis caused destruction of lung tissue and even if temporary arrest of the disease was secured cure was not certain.

Dr. MCCALL ANDERSON (Glasgow) said that for diagnosis tuberculin was invaluable, and therapeutically in external tuberculosis it was nearly always beneficial. In internal tuberculosis the relapses were caused by something else besides tuberculin

Dr. A. K. STONE (Boston) gave the history of the injection of tuberculin upon himself with uncertain results.

Dr. E FRANCE (Claybury) had inoculated 75 patients, and he concluded that the value of tuberculin in diagnosis was very great.

Dr. E. OTIS (Chicago) asked Professor Koch the reason of syphilitic patients sometimes reacting to tuberculin.

Dr. W. R. HUGGARD (Davos) related the histories of cases of phthisis which became far worse after the injection of tuberculin.

Professor W. NOLAN (Leyden) said that if patients were at work a rise of temperature was not necessarily a sign of mixed infection

Dr HERON said that he had never known a reaction to tuberculin in a syphilitic patient who was not also the subject of tuberculosis

Professor KOCH ended the discussion and stated that the tuberculin was from human tubercle bacilli Reaction occurred both in man and in cattle The two bacilli were not the same, but had a common "group" reaction. In treatment with tuberculin the patients should be in bed There should be no antagonism between treatment by tuberculin and out-door treatment, they should be carried out simultaneously

Dr S ARLOING and Dr P COURMONT (Lyons) then communicated a paper on

Technique and Results of the Serum-Diagnosis in Tuberculosis,[1]

of which the following is an abstract The employment of homogeneous cultures of the bacilli of human tuberculosis in glycerinated broth offered a means of investigating the agglutinising power of secretions and especially of the serum in tuberculous animals and men. In this sense the serum-diagnosis of tuberculosis was an easy and rapid method and one absolutely innocuous to the patient The only real difficulty consisted in obtaining cultures suitable for the purpose Their researches in the most varied cases of human tuberculosis showed that a positive serum reaction in a suspected subject would be a most valuable sign in establishing the existence of visceral uberculosis A negative reaction in a suspected case would elp in excluding a diagnosis of tubercle The serum-diagnosis of tubercle was therefore most valuable, especially in the preliminary diagnosis in cases suspected of early pulmonary lesions Many authors had verified and confirmed these facts—Ferré, Mongour, and Buard at Bordeaux, Mosny in Paris; Bendix and Romberg in Germany, and others But some others had not succeeded in keeping the homogeneous cultures or, at least, had not achieved satisfactory results in their use This was doubtless owing to the variations in the properties of the cultures in the hands of different experimenters and to the difficulty of estimating, in the cultures, the conditions favourable to agglutination To obviate these difficulties they had for some time past employed cultures, the growth of which had been arrested by the use of formol at the time when they presented the most favourable conditions Large quantities of cultures ready for use might thus be prepared, nd would retain their properties for a long period It was asy to send such cultures, specially adapted for serum reactions, long distances, and thus to make a large number of ctions with an agglutinable material of an identically similar kind By using these formolin cultures, the properties of which were standardised once for all, they had obtained still more exact results, completely confirming the conclusions set forth above Serum-diagnosis, by the use of homogeneous liquid cultures, might be of great assistance in the diagnosis of the nature of surgical lesions. The following were the statistics of the results of 66 observations

	Positive reactions	Negative reactions
Non tuberculous lesions: 11 cases	0	11
Lesions clinically tuberculous: 55 cases	41, or 74·54 per cent	14, or 25·66 per cent

These 66 patients all belonged to the surgical division The tuberculous subjects showed most diverse localisations osteo-articular, osseous, glandular, and cutaneous It had seemed to them that the serum reaction was more constant and frequent in cases which ran a favourable course, and that the graver cases gave a larger number of negative reactions So that from a practical point of view a positive serum reaction was a sign of great value in favour of the existence of surgical tuberculosis

Dr ALBERT ROBIN (Paris), Member of the Academy of Medicine, Delegate of the Academy of Medicine of Paris, read a paper on

The Nature and Diagnosis of the Habitat in Tuberculosis Therapeutic Considerations,

of which the following is an abstract He said that the prophylaxis of tuberculosis did not consist solely in the measures taken, either publicly or in private, against the infective agent A study of the respiratory exchanges enabled one to recognise predisposed subjects beforehand and consequently to submit them to a hygienic and therapeutic regimen capable of modifying the functional and nutritive fault which was the necessary antecedent condition for the development of the bacillus The respiratory exchanges were increased in 92 per cent of the subjects of confirmed tuberculosis and in 63 per cent of those with a tuberculous heredity Alcoholism and the different forms of overwork increased the respiratory exchanges and were capable of creating a soil for tuberculosis in the same way as heredity An examination of the respiratory exchanges, therefore, enabled a diagnosis of tubercle to be confirmed in doubtful cases The action of different drugs and methods of treatment on the respiratory exchanges enabled one to select those which were capable of modifying the soil and opened up a new mode of prophylaxis as well as of treatment in tuberculosis

Dr G E PAPILLON (Paris), consulting physician to the Hospital Lariboisière communicated a paper on

The Hereditary Arthritic Forms of Pre tuberculosis

In heredo-arthritic people, he said, the pre tuberculous stage might be disclosed by any arthritic manifestations, such as fits of asthma, attacks of subacute rheumatism, late appearance of "*stigmates de l'arthritisme*" These were not tuberculous localisations as the "tuberculous rheumatism" described 10 years ago by Poncet, but only effects of the bacillary toxins These fits of asthma, rheumatic attacks, arthritic deviations, &c, were the symptoms of hereditary disorder They affected the contractibility of the bronchial muscles, the secretion of the articular synovia, or the nutrition of the bone ends cartilages, and peri-articular muscles; they were manifestations of a sympathetic reaction to tuberculous intoxication.

Dr SAMUEL BERNHEIM (Paris) communicated a paper on

The Transformation of Tuberculous Soil Deficient in Acidity into an Arthritic Soil with Excess of Acid

He commenced by studying the character of the tuberculous soil, the bio chemical condition of which should be well known to everyone at the present day The measure of the mineral richness and of the chemical condition of the organism might in some degree be the measure of its resistance But they knew that the tuberculous patient possessed a soil deficient in mineral constituents, wanting in chlorides, lacking phosphates and above all deficient in acids, whilst the arthritic patient had a soil that was over-mineralised, exceedingly rich in chlorides and super-abundant in acidity That was to say, in chemical language, these two soils were in inverse proportion to one another Similarly from a clinical point of view, there existed a kind of antagonism between tuberculosis and the arthritic diathesis Phthisis was rare among arthritics and of benign manifestation in them From these first data—chemical biological, and clinical—Dr Bernheim drew numerous therapeutic deductions It was thus according to him, that the system of sanatoria the absolute rest, the abundant feeding the high altitude cure had no other end and no other effects than the transformation of the soil All these beneficent factors which had less effect on the bacillus than on the general system, tended to increase the organic acidity of the patient In fact, Dr Bernheim had submitted a certain number of patients to complete repose, and he had proved in their case, at the end of a certain period the existence of a very evident increase in urinary acidity Similarly the meat cure, so highly recommended by M Richet and M Héricourt, did not act by means of antitoxins but by a transformation of soil the acidity of which they enriched After having thus given an interpretation of facts Dr Bernheim added that it was possible to obtain this transformation of soil especially in the case of tuberculous patients who were treated early, by a hygienic and dietetic regimen and by saturating the general system with a powerful acid, such as phosphate of creosote or phosphoric acid At the Anti-Tuberculous Dispensary of Paris he had observed a large number of patients in whom he had frequently estimated the urinary acidity Now he had proved that under the influence of phosphate of creosote taken in doses of three grammes every two days the acidity rapidly increased and the general condition improved hence they were right in concluding that it was possible, by artificial methods, to transform a soil deficient in acid and favourable to tuberculous evolution into a hyperacid soil and one that was antagonistic to Koch's bacillus. This transformation, which was, according to Dr. Bernheim, the sheet-anchor of the subject of phthisis, should be sought by means of, and perhaps obtained by, a hygienic and dietetic regimen, as well as by powerful therapeutic measures.

[1] VIIe Congrès pour l'Étude de la Tuberculose, Berlin, 1899; Zeitschrift für Tuberculose und Heilstättenwesen, 1900, Band III, and Gazette des Hôpitaux, Dec. 1st, 1900

Dr. E. MOSNY (Paris) communicated a paper on

Para-Tuberculous Hereditary Dystrophy.

Clinical study and experimental medicine, he said, demonstrated the fact that subjects of phthisis did not transmit the bacillus of tuberculosis to their offspring, and that the very rare cases of congenital tuberculosis were due to intra-uterine contamination of the fœtus by the tuberculous mother. Clinical observations, moreover, went to prove that subjects of phthisis did not transmit to their offspring either a specific predisposition to bacillary contamination or any marked degree of immunity. But they should not, however, conclude from this that tuberculosis of parents exercised no influence on the health of their offspring. Both clinical and experimental medicine, indeed, agreed in demonstrating that the tuberculosis of parents had an influence on fecundity and the products of conception similar to that which was exercised by the majority of chronic intoxications. These consequences, early or late, of the tuberculosis of parents on their future descendants might be conveniently grouped under the title "Para-Tuberculous Hereditary Dystrophy." Their frequency was a witness to the grave evil or tuberculosis from a social point of view. Generalised manifestations of hereditary dystrophy appeared at all stages of existence; from conception, or during the course of pregnancy, they were shown by sterility, death of the fœtus, abortion, and premature birth; when pregnancy arrived at its normal limit, by still-birth, weakness of the offspring, which was reared badly, pined away, and died prematurely without adequate cause, or, indeed, survived in a piteous condition, badly or incompletely developed, a fit subject for all forms of decay, and exposed without defence to all kinds of contamination. At other times the influence of the tuberculosis of parents on the health of their offspring localised itself, or showed itself under multiple forms of most varied manifestation, the consequences of arrest or perversion of normal development. Among these localised manifestations of para-tuberculous dystrophy the following appeared with a frequency that was very marked. hypoplasias of the vessels and blood, pure mitral stenosis, stenosis of the pulmonary artery, generalised stenosis of the arteries (arterial aplasia), and chlorosis. Generalised or localised manifestations of para-tuberculous hereditary dystrophy, and the functional troubles which sometimes depended on them, became apparent, either at birth or not till later at one of the important stages of growth—e.g., weaning, dentition, or puberty. Tuberculosis of the father or that of the mother, above all the latter, was the determining course of these dystrophic congenital defects. Tuberculosis of the parents no more predisposed the offspring to bacillary contamination than it conferred immunity against attack. But the offspring of phthisical subjects, organically and functionally imperfect, weak from the time of birth, and more tried than others by the vicissitudes of growth—seemed to be predisposed to bacillary infection, because the risks of contagion were multiplied infinitely by contact, immediate and continuous, with contaminated parents, and because their weakened frame offered less resistance to the infection so produced. The apparent immunity of some descendants of tuberculous subjects who carried with them certain manifestations of para-tuberculous hereditary dystrophy, was, in reality, the consequence of the very nature of the dystrophic lesion or of its localisation and not the manifestation of a real condition of resistance. Such was the relative immunity in regard to tuberculosis exhibited by the subjects of chlorosis or pure mitral stenosis

A paper by Dr. P. HAUSHALTER and Dr. A. FRUHINSHOLZ (Nancy) was communicated entitled:

The Frequency and Significance of Tuberculosis of the Tracheal and Bronchial Glands in Miliary Tuberculosis of Children and in Tuberculous Meningitis

In 78 necropsies of miliary tuberculosis in children below 12 years of age tuberculosis of the tracheal and bronchial lymphatic glands was met with 74 times (about 95 per cent.); in 67 cases there was tuberculous meningitis, and in 64 of these affection of the glands was present. This glandular affection had always the character of an old and caseous tuberculosis; in 29 cases it coincided with old tuberculous lesions of the lung, generally localised; in 44 cases it formed the only old tuberculous lesion present. [illegible] all cases, therefore, the origin of the [illegible] which ended in the miliary [illegible] caseous tracheal a[illegible] this lesion was a pr[illegible] of tuberculosis in ch[illegible] tion of glands, wh[illegible] seated in the miliary [illegible] end in the bacillary [illegible] sidered almost the sol[illegible] meningitis? In spit[illegible] form and vessels at the base of [illegible] relations of mediastinal glands—re[illegible] masses of [illegible] which were shown by drawings exhibited—they had failed to find, macroscopically or microscopically, any lesion of the walls of the vessels that could explain the direct passage of the [illegible] from the lymphatic glands into the blood. The bacillary infection of the blood took place through the [illegible] system. In the very brief time occupied by the passage of the bacillus-bearing leucocytes from the caseous lymphatic glands of the mediastinum [illegible] the blood-stream, passing as they did by efferent lymphatics, by a short section of the thoracic duct or of the lymphatic trunks—the destruction of the bacilli had time to be effected. Even in many of the cases in [illegible] pure meningitis existed without ger[illegible] and in which a person would therefore be tempted to [illegible] for the origin of the infection not in the blood-vessels but in the lymphatics, it was probable that there existed a general bacillary infection, the manifestations of which [illegible] not appreciable to the naked eye or w[illegible] This they had been able to prove [illegible] occasions [illegible]

On the Value of the Rectal Tem[illegible]

Mr. C. BRAINE-[illegible] Cotswold Sanatorium [illegible] communicate[illegible] the rectal temperature was most im[illegible] of the activity of tuber[illegible] giving a prognosis. [illegible] activity of the disease [illegible] showed no rise of te[illegible] showing how valueles[illegible] therefore misleading.

THUR[illegible]

Sanatori[illegible]

A discussion upon thi[illegible] CLIFFORD ALLBUTT (Ca[illegible] J. KINGSTON FOWLER [illegible] burgh). A report em[illegible] treatment in England wa[illegible] (Norwich), who had draw[illegible] it up. Among the papers contributed to the section may be mentioned: A Plea for Sanatoria, especially for the Prevention and Treatment of Scrofulous Complaints, by Sir HERMANN WEBER; The Open-air Treatment in Institutions and in N[illegible] Homes, by Dr. E. SYMES THOMPSON (London); The Sanatoria at Cannes, by Dr. BARADAT (Cannes); Results of Sanatorium Treatment in Poorer Patients, by Dr. JANE WALKER (London); The Alice-Fagniez Sanatorium at Hyères, by Dr. EMILE VIDAL (Hyères); The [illegible] Hospital at Havre, by Dr. FROTTIER (Havre); The [illegible] of Consumption in the Halifax Poor-law Union, by Dr. T. DOLAN (Halifax); The Gorbio Sanatorium at [illegible] Dr. MALIBRAN (Mentone); and The Responsibility of [illegible] Medical Profession with regard to Cases of Tu[illegible] by Dr. N. D BARDSWELL (Aberdeen).

SECTION III.

PATHOLOGY, INCLUDING BACTERIOLOGY.

TUESDAY, JULY 23RD.

The meetings of this section were held in the [illegible] Hall, Langham-place, under the presidency of [illegible] G. SIMS WOODHEAD, M.D. Edin., F.R.S [illegible] Pathology in Cambridge University.

Dr. ALFRED MOELLER (Berlin) and L[illegible] (bacteriologist to the London Hospital [illegible] on

The Morphological and Physiological Variatio[illegible] *Bacillus Tuberculosis and its R*[illegible] *Acid-proof Bacilli and (b)* [illegible] *and other Strept*[illegible]

Dr. Moeller's contribution will [illegible] p 204 of this issue of *THE LANCET* Dr Bulloch said that so far as was known the bacillus tuberculosis discovered by Koch was the only immediate cause of all forms of human tuberculosis In the majority of cases the micro organism was met with in the form of slender rods which frequently showed clear spaces in their interior Under certain conditions which were at present imperfectly understood the micro organism might show filaments, true dichotomous branching, and club formation and, in the tissues, especially in experimental tuberculosis, it might assume a radiate arrangement—characters which from a *taxonomic point of view brought it into close relation* with a large group of micro-organisms variously designated streptothriceæ, oospora, nocardiaceæ, and more recently actinomycetes (Lachner-Sandoval) According to all experience, the tubercle bacillus was an aerobic facultative parasite which grew extremely slowly outside the body and for its growth required a relatively high temperature, the minimal and maximal limits of which were 29° C and 42° C This [illegible] the tubercle bacillus [illegible] temperate climates [illegible] obtain and were best *prepared by growing the organism upon relatively com*plicated media such as blood serum The addition of glycerine to all media undoubtedly favoured the development and luxuriance of the cultures In the presence of this substance, however, good growths could be obtained in vegetable media, such as potato (Pawlowsky, Lubinsky, and others) It was also possible to obtain growths on media which contained no proteid material, the carbon and nitrogen demands of the organism being fulfilled respectively by ammonia salts and glycerine Hitherto in such simple media it had not been possible to replace the glycerine by other allied compounds (Proskauer and Beck) With ordinary hydro-alcoholic solutions of basic anilin colours the tubercle bacillus was stained with extreme difficulty and imperfectly If certain substances (anilin, para-toluidin' meta toluidin, benzaldehyde, carbolic acid—in practice the latter was chiefly used) were added to the basic dyes the penetrating power of the latter for the tubercle bacillus was increased in high degree, and on subsequent treatment with mineral acids (33 per cent. nitric acid, 25 per cent sulphuric acid) the colour remained in the bacilli, so that they stood out prominently from other objects in the association with which they might be. This "fastness' towards acids (Säurefestigkeit), discovered by Ehrlich, had had a great influence on the development of the study of tuberculosis and at the present day the microscopical diagnosis was made with this method alone. The acid fastness was, however not specific to the tubercle bacillus, but was also possessed by a considerable number of other bacilli, some of which were pathogenic for man (bacillus lepræ) and some for animals In recent times the number of these had been considerably increased, and although they had been found as saprophytes and capable of living at relatively low temperatures they might produce tubercle-like diseases in animals The *microscopical diagnosis alone* was not sufficient to differentiate the true tubercle parasite from other "acid fast" organisms. There was every reason to believe that the bacilli of human and bovine tuberculosis were identical. The bacillus of avian tuberculosis presented points of difference, but these were not differences of species There existed a group of acid fast, tubercle-like bacilli widely distributed in Nature. The identity or non identity of these with Koch's bacillus was not proven. In any case, a microscopical diagnosis of Koch's bacillus, especially in objects which were from their nature and source liable to contamination with other acid-fast bacilli was not decisive by itself [illegible] ohol subsequently to acid was not [illegible] the tubercle bacillus from others [illegible] bacilli might be as *säurefest* and *alcoholfest* as Koch's bacillus Contrary to former beliefs the acid fastness was not due to the presence of fat in the bacillus as after complete removal of this substance the bacilli were still acid- and alcohol-fast. The acid fastness was due to a body of the nature of a wax (Aronson) which could be extracted by acid-alcohol-ether, boiling chloroform and boiling benzene. This wax in itself was powerfully acid fast, but was unstainable by fat stains. (Sudan III and Ponceau R) *Besides* wax and fat, which were present in relatively large amount, the tubercle bacillus was composed of proteids (important among which was a variety of nucleic acid described as tuberculinic acid—Ruppel) and salts (with phosphates predominating) After the removal of all proteids, wax, and fat, a substance remained which contained a considerable quantity of nitrogen and from its reactions was probably chitin or some allied body No certain facts were known of the possession or non-possession by the tubercle bacillus or other acid fast bacilli of true endospores Although the tubercle bacillus was more resistant to injury than non sporing microbes, it was much less resistant than true endospores

Professor J G ADAMI (Montreal) thought from the study of the cultures in the museum of the Congress that the time had hardly arrived to lay down definite laws as to the identity or otherwise of the *acid* fast bacteria. Too much stress could not be laid upon the recommendation of the American committee that all bacteriologists should work with standard media and he felt sure that the solution of the problems would be found in following those lines

Dr E J MCWEENEY said that the inter relationships of the acid fast bacteria were so extremely complex that it was as yet not possible to pronounce upon the individuality of the tubercle bacillus and he agreed that the tubercle bacillus was closely allied to the streptothrices

Professor MARMOREK, director of the Institut Pasteur in Paris *drew attention to the increasing number of acid-fast* bacteria which were being discovered. The close resemblance between the external appearances of these acid fast bacteria made it necessary to be very careful in drawing distinctions between the tubercle bacilli and the para-tubercle bacilli It was the duty of every bacteriologist to endeavour to simplify the question as much as possible

Dr H KOSSEL (Berlin) quoted some experiments of Dr Weber concerning the identification of the tubercle and pseudo tubercle bacillus. According to his experience, no acid fast bacterium which was not the tubercle bacillus produced after injections into animals progressive tuberculous lesions, such as those produced by the true tubercle bacillus

Dr WILLIAM BULLOCH, in his reply, agreed with Dr Kossel in that the injection of acid fast bacteria other than tubercle bacilli injected into animals in the laboratory did not, in his experience lead to tuberculous lesions He held that it was possible to diagnose tubercle bacilli by inoculations and subsequent cultures from the inoculated animals

Infectivity of Milk

Dr LYDIA RABINOWITCH (Berlin) read an interesting paper on the Infectivity of the Milk of Tuberculous Cows, the Reliability of the Bacteriological Diagnosis, and its Practical Importance in the Extirpation of Bovine Tuberculosis. In 1899 the author, in conjunction with Dr W Kempner, showed that tubercle bacilli could occur in the milk of animals suffering from latent tuberculosis where the disease could only be detected by means of tuberculin She considered the only reliable test of the presence of tubercle bacilli in milk to be the animal experiment, and concluded by stating that the frequency of tuberculosis among calves, as well as the great increase among swine in recent years, *offered the best proof* of the assertion that the milk of tuberculous animals was the chief cause of the dissemination of tuberculosis among them

Dr J E. MCWEENEY bacteriologist to the Local Government Board of Ireland read a paper on the Infectivity of the Milk of Cows which React to the Tuberculin Test in the absence of Clinical Evidence of Tuberculosis in which he said that from his experience with herds of high-class dairy cows he came to the conclusion that tuberculous mammitis was a rare disease among cattle even although the cows suffered from other forms of tuberculosis Sixteen cows suffering from tuberculosis but without lesions of the udder were made the subjects of experiments The milk of these cows was frequently examined for tubercle bacilli but without any success The persistent negative results led him to suppose that in retailing milk tubercle bacilli found an entrance from dirty pails from sputum or from other sources

Professor NOCARD (Alfort) considered that milk produced by a cow the subject of tuberculous mammitis was free from danger for the calves but was the source of the greatest danger for pigs especially in the countries where the production of butter and cheese was considerable

Professor J G ADAMI pointed out that even if the measures adopted saved only a minute proportion of the helpless infants it was the duty both privately and publicly to take every step necessary for the salvation of that minute proportion.

Professor Hamilton (Aberdeen) raised the question as to whether a calf became tuberculous when suckled by a cow the subject of tuberculosis but with sound udders. The experience in Aberdeen was that calves fed under these circumstances did not become tuberculous.

Dr. Ravenel (Philadelphia) said that the feeling among workers in Philadelphia was that the tubercle bacilli could pass into the milk through a perfectly sound udder when the cow was suffering from tuberculosis elsewhere. In America the tuberculin test was looked upon as practically the only method of diagnosis.

Professor Sims Woodhead (Cambridge) felt strongly, despite much that had been said to the contrary, that if a cow suffered from mastitis and gave the tuberculin reaction the milk from that cow should be condemned or sterilised. He was certain that in many cases the tubercle bacilli could not withstand the action of the alimentary canal, but could find an entrance through the tonsil.

Professor B. Bang (Copenhagen) thought that it was very unfair to condemn the milk of a cow with sound udders which happened to give the tuberculin test, as he did not think that such a cow would yield tubercle bacilli in sufficient numbers to be harmful.

On Wednesday, July 24th, this section sat in conjunction with Section II.

Thursday, July 25th.

The Varieties of Tuberculosis.

Professor Benda (Berlin), Professor Delépine (Manchester), and Professor D. J. Hamilton (Aberdeen) opened a discussion on this subject.

Dr. Tatsusaburo Yabé, principal medical officer of the Japanese Navy, read a paper upon

Immunity in Tuberculosis,

in which he gave an account of his own researches in respect of the sero-therapy of tuberculosis. When, said Dr. Yabé, Professor Koch made his famous discovery in 1890 of the influence exercised by previous tuberculosis upon consecutive inoculation, and proved this influence by experiments upon guinea-pigs, he demonstrated the possibility of securing immunity from the disease. In the laboratory of Dr. Roux at the Pasteur Institute in Paris Dr. Yabé, in 1898, made certain researches into the existence and nature of this immunity. Tuberculin he saw to have no immunising action, and he sought to separate other toxins which would account for the phenomena of tuberculosis. He obtained three substances from the bacillary bodies: (1) the waxy substance discovered by Aronson; (2) a body which he called "tuberculo-mycoprotéine"; and (3) a body of undetermined chemical character, "tuberculo-bactéricidine." He found both the latter two substances to give immunity, but the "tuberculo-mycoprotéine" was not so effective as the "tuberculo-bactericidine." From his work he came to the conclusions that the disease was curable, that immunity against tuberculosis could certainly be obtained, and that protection could be secured by "vaccination," but he was not prepared as yet to practise the injection of the new substances which were very toxic. The direction of his further researches would be towards obtaining a serum which should be antitoxic as well as bactericidal.

SECTION IV.

Tuberculosis in Animals.

Tuesday, July 23rd.

The meetings of this section were held in the Marlborough Hall, Regent-street, W., under the presidency of Sir George Brown, C.B, the Governor of the Royal Veterinary College.

The Diagnosis of Tuberculosis in Animals during Life.

A discussion upon this subject was opened by Professor Dewar, Principal of the Royal (Dick) Veterinary College, Edinburgh.

Professor Dewar said that increased experience led him to believe that the number of tuberculous cows affected with tubercle of the udder was greater than that usually estimated—i.e., about 3 per cent. For the successful use of tuberculin as a diagnostic agent several things were required: first, a thoroughly reliable tuberculin; secondly, that the herd to be tested should be kept quiet and undisturbed; and thirdly, that the veterinary surgeon should be allowed freedom and facility in the application of the test. When every precaution was taken and the test carefully supplied at least 90 per cent. of the results would be correct and definite.

Wednesday, July 24th.

Tuberculosis and the Milk-supply.

Mr. John A. W. Dollar (London) opened a discussion by reading a paper on the above subject of which the following is an outline:—The relations of bovine and human tuberculosis and their intercommunicability. Transmission of bovine tuberculosis to man; necessity for a certain concentration of the bacilli in transmission by the digestive tract. Reservations in regard to accepting results of inoculation and feeding experiments in rodents as applicable to man. Intestinal tuberculosis in children; rarity of primary tuberculosis of the bowel in children and in men; possible reasons for this. Bovine tuberculosis in Europe; proportion of tuberculous cows as shown respectively by slaughter-house statistics and by tuberculin test; proportion of cows with tuberculosis of the udder. Tuberculosis common to goats, asses, and sheep, as well as to cows. Detection of tubercle bacilli in milk as sold. Methods of preventing the spread of tuberculosis by milk. Sterilisation and pasteurisation of milk, their advantages and drawbacks. Examples of commercial establishments supplying pasteurised milk. Sterilisation of milk on a commercial scale. The eradication of tuberculosis from herds of milch cows. Examples of commercial establishments supplying milk from guaranted tubercle-free herds; their success. Improved hygienic treatment of milch cows; Bang's system of stamping out tuberculosis. Experiments on Bang's system in Belgium, Canada, and the United States of America. Tuberculosis in New Zealand. Legislation in regard to milk traffic proposed by German Milk Trade Union.

Mr. Eaton Jones (Liverpool) advocated the practical measures which have to be employed to get rid of the danger to human life and health in the use of tuberculous milk. He said that whatever loss the farmer had to incur for the good of the public should be made good to him by the public purse. He had very great doubts on the propositions made by Professor Koch on the previous day, and they ought to go on protecting the public from this insidious disease as they had begun to do.

Professor McLauchlan Young said that he had long held that it was surprising that the authorities should be so strict in their inspection of meat and so lax in their inspection of milk. It would be of material aid if they had power to apply the tuberculin test to dairy animals.

Mr. James Laithwood (Cheshire) said that so far as the milk-supply was concerned it was an easy matter to prevent the disease. He recommended the establishment of a State veterinary service as had been instituted in Italy. He would include the disease in the Contagious Diseases (Animals) Act, and was of opinion that only a qualified veterinary surgeon should be permitted to use tuberculin on animals. He thought that the public ought to pay for the services of these qualified men, as they were the people who benefited by it. He pointed out that it did not follow that because a cow had no appearance of a diseased udder its milk was perfectly safe for consumption. He concluded by referring to the work of the Manchester Dairy Milk-supply Company.

Professor Stockman did not consider that sufficient provisions were made to prevent improper milk-supply. All udder disease should be notified. The inoculation of animals was not a practical measure. As regards compensation the dairymen would not accept any scheme that would not involve the expenditure of impossible sums of money.

Professor Owen Williams (Edinburgh) said that of the ox tribe the cow was undoubtedly the centre of infection of tuberculosis. He had pointed out some years ago that tuberculin was being used fraudulently, and he recommended then and now that tuberculin should be registered as a poison and should be sold only to practitioners who were going to make use of it for honourable purposes. He advised that local boards should be appointed for the purpose of paying compensation money promptly.

Mr. Montefiore (Belgium) said that a great deal depended on the quality of the tuberculin, which was not always perfect. He recommended the use of goat's milk for tuberculous patients. In a sanatorium these animals might be kept with a great saving of expense by the authorities. They had found in Belgium that it was almost impossible to inoculate tuberculosis in goats. The odour of goat's milk prejudiced people against it, but this could be easily got rid of.

Professor J WORTLEY AXE (British Dairy Farmers' Association) said that before the words of so eminent a man as Professor Koch went out to the world his statement ought to be scientifically proved and demonstrated If they were to mitigate the prevalence of the disease they must observe more the laws of nature and permit the animals to live out of doors instead of in overheated byres Of course the milk supply was a great objection, as it would undoubtedly be much less, but the gain would be more than equivalent in the health of the animals

Professor BANG said that for the past three years they had had a law in Denmark by which all cows with udder disease were ordered to be killed Great care was taken in the detection of the disease With such a law in existence it was necessary to have scientific stations where the samples of milk could be properly examined. If necessary, in a doubtful case especially, more than one sample should be examined and these at intervals sufficiently long the milk *in the meantime* of the doubtful cow being boiled before being sold He referred to the frequency of the existence of tubercle bacilli in tuberculous cows which had no disease of the udder He thought that it was best for the cows to be out in the air for the whole year

Mr E G EASTON (London County Council) said that an examination of the cows in London ordered by the London County Council showed that only half per cent was found to be suffering from tuberculous udders and that number was greatly decreasing He had grave doubts, seeing that people connected with cows were the healthiest people of the communicability of the disease from an animal to man Cows in proper sheds could be kept in a perfectly healthy condition and there was no need for them to live in the open air all the year to say nothing of the fact that the climate was too severe in the winter The boiling of milk was absurd

Professor MCFADYEAN maintained that the appearance of emaciated tuberculous cows at the markets was far too common a sight It could never be absolutely demonstrated that it was impossible to transmit the disease from animal to man because the latter would not submit to it and that was the only way in which it could be absolutely proved In spite of this there was ample reason why they should concern themselves with the milk supply and its control He thought that Mr Easton had misunderstood what Professor Koch had said and referred him to the latter s paper which he quoted Mr Easton had confused the transmissibility of bovine tuberculosis to man with the transmission of human tuberculosis to bovines

Mr CROWHURST referred to the importance of a pure water supply to the cows and of good surface drainage to the sheds Cows could not make pure milk from impure water

Professor DEWAR insisted on the necessity of further legislation in connexion with the milk trade At present by an extension of the Dairy and Cowsheds Act inspectors could put out of the shed such cows as were affected with tuberculous udders but that was all that could be done

Professor CROOKSHANK did not consider that the statement he had made some years ago had been in the least altered by the words of Professor Koch Professor Koch had based his conclusion on the negative results obtained upon inoculation of the cattle with bacilli from the human being He himself had in his experiments proved to his entire satisfaction that it was possible to infect an animal by transmission from man It was impossible to prove the reverse and therefore he took the position that there may be danger in tuberculous milk and meat and therefore they ought not to slacken their efforts to get rid of all such risk.

Mr CARLE and others also spoke, and Mr DOLLAR replied

THURSDAY JULY 25TH

Mr JAMES KING, Veterinary Inspector, City of London read a paper on

Tuberculosis and the Meat Supply

He said On being asked by your secretary to open this discussion on Tuberculosis and the Meat Supply I must say that at first I felt very reluctant to undertake it, my opinion being that it might have been placed in more able hands However having exceptional opportunities of making post mortem examinations on our food animals after duly considering the matter, I acceded to his request, in the hope that by so doing I might be able to give this Congress an idea of the prevalence of the disease and the enormous loss to the country through its ravages The subject that we have met to discuss to-day is one of great moment, not only to the meat trader but also to the profession generally Tuberculosis is the cause of great loss and dissatisfaction to the farmer and also to the meat trader, so much so that many of the latter, after endeavouring to the utmost to follow the trade of their ancestors, and to deal only in home fed meat, have found themselves compelled through losses arising from disease amongst their cattle, to abandon it The cases are rendered the more trying since neither expert nor trader can by ordinary inspection detect the malady in open market Inspection is now becoming more general and better trained and more qualified officers are appointed than was the case formerly The Health Acts, too are more stringent for the protection of the public The butcher therefore concludes that as there is no Act to protect him and as the passing of an animal by a veterinary inspector in an open market is no guarantee that what he purchased at a good price as sound and fit for human food will turn out to be so, or that money value will be realised, what is considered in his case as a trade risk is much too great and he therefore finds it necessary to protect himself by leaving live cattle alone and to obtain his supplies from the dead meat markets. Here he can select what suits his trade, without fear of confiscation and prosecution by reason of tuberculosis In our dead meat markets the home fed meat has to compete with the foreign which may be home killed or otherwise and if the supply of the former be limited or the price not suitable the butcher is tempted to purchase the latter, and invariably finds that he can do so to advantage The quality may be only slightly inferior or possibly equal to that for which he had been accustomed to take so much trouble and to run so much risk He consequently continues to purchase the foreign and his customers become educated to its flavour Thus, to the great detriment of our home supply he may be able to furnish them with apparently as good a joint at less cost for once the price of meat has been reduced it is difficult to raise it again This seriously affects the farmer and the tradesman for in the first instance the home animal has to be raised and fed at considerably greater expense than its foreign competitor and the butcher in addition to the risk of losing the carcass through its being a subject to tuberculosis, finds it harder still to make his purchase at a rate which will protect him from serious loss He knows from experience that no matter what class or breed he may buy the risks are identical His ox may cost £30, and yet after slaughter not infrequently the carcass is found to be so extensively pervaded with tuberculosis as to render it unfit for human food and it therefore has to be condemned It is common knowledge that a very large percentage of cattle in our best herds are subjects of the disease and further that it is impossible by ordinary examination to find any clinical evidence of the malady I have had occasion to make post mortem examinations of some of the best cattle our country produced which were exhibited as such at our principal shows After slaughter it has been absolutely necessary to condemn parts of them on account of tuberculosis This has been a well known fact for many years past and yet nothing of any consequence has been done to check the prevalence of this scourge although it is generally admitted to be one of the sources of infection to human beings and the means of mitigating the evil are placed in our hands A few stock holders capable of affording it have made voluntary attempts to remedy the state of things but their small efforts although demonstrating what might be done if powers were granted by Act of Parliament, do nothing to check effectually the ravages of the disease or to restore the lost confidence of our meat-traders To these agriculturists must look, for unless they can find purchasers for their cattle at remunerative prices it is of no use for them to rear and to feed stock. I have been a veterinary inspector now for over 10 years and for six of them I had the supervision of a large provincial meat market From careful observation I have come to the conclusion that there is a growing demand for foreign meat and a corresponding decrease as regards home fed The reason given by the salesman is invariably that the loss is so great through having the carcasses of home-fed cattle they buy condemned on account of their being affected with tuberculosis that they are driven to the purchase of the foreign Surely this being the case, it points to the necessity for some action being taken by the Government To realise the extent to which some of our cattle suffer from this disease it is necessary to be present when they are slaughtered. Sights are then seen which make one wonder how, large as the death roll is from this cause, the disease is not more prevalent in human beings, and the urgent need for proper and systematic inspection under definite laws relating both to live animals and carcasses, together with State aid by way of compensation, is obvious. With the object of ascertaining as near as possible the percentage of cattle affected with tuberculosis, the loss to the country, and the quantity of meat rendered valueless to all concerned in the matter I have made searching post-mortem examinations as follows:—

TABLE I.—RESULT OF THE POST-MORTEM EXAMINATION OF 1738 ANIMALS, CONSISTING OF COWS, BULLS, OXEN, HEIFERS, AND CALVES.

—	Cows.	Per cent.	Bulls.	Per cent.	Oxen.	Per cent.	Heifers.	Per cent.	Calves.	Per cent.	Total.
Number of carcasses and organs examined	500	—	113	—	131	—	53	—	941	—	1738
Number of carcasses free from disease	266	53·2	93	82·3	116	88·55	42	79·24	929	98·72	—
Number of carcasses tuberculous	234	46·8	20	17·7	15	11·45	11	20·75	12	1·27	292
Number of carcasses with lesions in abdominal and thoracic regions	129	25·8	9	7·96	9	6·87	8	15·09	—	—	155
Number of carcasses with lesions in thoracic region only	87	17·4	7	6·19	3	2·29	3	5·09	—	—	100
Number of carcasses with lesions in abdominal region only	18	3·6	4	3·0	3	2·29	—	—	—	—	25
Number of carcasses with lesions in mammary glands	11	2·2	—	—	—	—	—	—	—	—	11
Number of carcasses with lesions in testicles	—	—	1	0·87	—	—	—	—	—	—	1
Number of carcasses affected	67	13·4	5	4·42	6	4·58	5	9·43	5	0 53	88
Number of carcasses totally destroyed	35	7 0	3	2 66	1	0·76	1	1·88	2	0·21	42
Number of carcasses partially destroyed	32	6 4	2	1·77	5	3·81	4	7·54	3	0 21	46

NOTE.—All percentages calculated on the number of carcasses examined.

TABLE II.—WEIGHT AND VALUE OF MEAT AND VISCERA DESTROYED.

—	Weight of meat in pounds.	Price per pound.	—	Number of whole viscera destroyed	Price each.	—	Number of abdominal organs destroyed.	Price each.	—	Number of thoracic organs destroyed.	Price each.	—	Total Value.
		d.	£ s. d.		s. d.	£ s. d.		s. d.	£ s. d.		s. d.	£ s. d.	£ s. d.
Cows ...	16,832	4	280 10 8	129	16 6	106 8 6	18	14 0	12 12 0	87	2 6	10 17 6	410 8 8
Bulls ...	2,376	4½	44 11 0	9	16 6	7 8 6	4	14 0	2 16 0	7	2 6	0 17 6	56 13 0
Oxen ...	1,152	5½	26 8 0	9	16 6	7 8 6	3	14 0	2 2 0	3	2 6	0 7 6	36 6 0
Heifers ...	748	5½	17 2 10	8	16 6	6 12 0	—	—	—	3	2 6	0 7 6	24 2 4
Calves ...	480	4½	9 0 0	2	5 6	0 11 0	10	2 6	1 5 0	2	3 6	0 7 0	11 3 0
Total ...	21,588	—	377 12 6	157	—	128 8 6	35	—	18 15 0	102	—	12 17 0	537 13 0

The above condemnations have been made in accordance with the recommendation of the Royal Commission on Tuberculosis. What the loss would amount to if the carcasses of all animals affected with the disease were destroyed, as is recommended by some authorities, I must leave you to conjecture. With reference to the above tables I have taken great care to see that all the meat condemned was weighed, with the exception of the calves, and the figures enumerated are taken from average wholesale prices in the trade. In estimating the prices of viscera I have taken the figures from wholesale prices given by offal contractors, *plus* the price of fat. averaging four stones per beast at 1*s.* 6*d.* per stone. This is always destroyed with the viscera in cases of tuberculosis. The figures in the table relating to calves were obtained from Mr. W. F. Shaw, F.R C.V.S., who made the post-mortem examinations on behalf of the Local Government Board, in order to ascertain their freedom from tuberculosis. The whole of the carcasses were inspected by me, and although a record of those affected with the disease was kept their weight was not taken. I have therefore simply given an ordinary average weight. In addition to the loss sustained, as set out in Table II., to form a proper estimate of the cost of this disease to the country, it will be necessary to include the amounts paid by local authorities for destroying such affected meat and offal, in order to comply with the Public Health Acts. These statistics would be very difficult to obtain, but would, I may mention in passing, total up to no small amount. Taking figures from the annual returns of the Board of Agriculture for Great Britain under the Diseases of Animals Acts for the year 1899, which are the last supplied to me, I find that the estimated number of cows in Great Britain was 2,670,260, and taking the average life of a cow at seven years, it may be argued that one-seventh of that number is killed annually—viz., about 381,608 Therefore, if from the above table the percentage of those so affected with the disease as to render the carcasses, &c, partially or totally unfit for human food be taken, we find by the simple rule of three that if a loss on 500 cows be £410 8*s.* 8*d.* the annual loss on cows will amount to £305,067. For the purposes of this paper let us now take the numbers from the same returns under the heading of 'Other cattle aged two years and upwards.' This will include bulls, oxen, and heifers referred to in my table, as those were over that age. The number given by the Board of Agriculture is 1,341,310, and calculating the average life of that class to be three years, one may estimate that one-third of that number is slaughtered annually—viz., 447,103. Therefore, by taking the percentage of those affected with the disease, as shown by the table, we find by the same deduction that if a loss on 297 be £116 1*s.* 4*d.*, the annual loss on cattle under this heading will amount to £174,726, making a total annual loss through this disease of £479,793. It is not necessary to take the loss in calves, as the percentage of disease amongst that class is so small that it may be looked upon in the ordinary course as a trade risk and need hardly have any effect upon our meat-supply. Can it be wondered from the foregoing figures (although approximate) that the trade in foreign meat has made such enormous strides within the last few years? If we refer to the agricultural returns of the Board of Agriculture for 1900 we find that under the head of fresh meat imports it is reported that a quota which formed only one-fifth of a single pound per unit of the population in 1866-1870 has expanded to little short of 20 pounds per head on the average of the five years 1896–1900, and has touched 22·5 pounds per person in the single year 1900, an instance of progress quite out of all proportion to the development of other forms of imported food. On again looking at the returns of the total number of cattle in this country for the last ten years, we find that the year 1900 shows a decrease, as compared with the year 1891 of 47,821 These figures denote that although our population is steadily increasing as are also our meat-eating propensities nothing is being done to supply the increased demand, with home fed cattle In our live stock markets at present, although returns show that supplies are not so plentiful as in previous years, there seems a difficulty in salesmen realising profitable prices for beef cattle In conclusion, I am convinced from personal observation that the principal cause for this state of things is tuberculosis, and we are not improving it by our present voluntary efforts to purify some of our stock by the use of tuberculin as this undoubtedly throws a much larger number of known tuberculous animals on the market and increases the risks of the butcher thus making the purchase of home animals more of a gamble than a legitimate trade Is it then surprising that he purchases foreign meat to supply his customers instead of the home article? I have endeavoured to place before you in these few remarks as clearly as I can in the time allowed the present state of affairs, which has now been going on for years and there can be little doubt that the cause is on the increase I cannot conclude without asking how long will this be allowed to continue in our midst before any active steps are taken to eradicate or even to reduce the prevalence of this disease

THE SOCIAL SIDE.

Sir James Blyth the honorary treasurer of the Congress entertained to dinner at 33 Portland place, on Monday July 22nd the Duke of Cambridge who had presided on the afternoon of that day at the opening ceremony of the Congress Sir James Blyth invited to meet his Royal Highness the President and mem[illegible] Council of the Congress, many of the [illegible] the foreign delegates [illegible] distinguished members, British and foreign, as [illegible] Prince Edward of Saxe Weimar the Duke of Northumberland, Earl Cadogan the Earl of Derby Lord Strathcona and Mount Royal and the Lord Mayor of London Covers were laid for about 60

On the same evening the members and delegates of the British Congress on Tuberculosis were entertained at the Queen's Hall, Langham place, by the President of the Council of the Congress and the executive officers The great hall was tastefully decorated with flowers and palms and the Royal Engineers string band played during the evening a varied selection of music There was a very numerous assembly of guests and the music was in consequence drowned by the buzz of conversation. In St George's Hall which adjoins the Queen's Hall Professor G Sims Woodhead of the University of Cambridge, gave a bacteriological demonstration illustrated with lantern slides His audience would probably have been larger if some means had been devised of informing the guests the way to the lecture-hall This same want of organisation also led to much disappointment among those who were desirous of hearing Professor McFadyean of the Royal Veterinary College deliver a discourse in the same hall An interesting event in the evening was an impromptu demonstration by Professor Koch of specimens and cultures in the Congress museum at the top of the building and those who by dint of much questioning did find their way there were well rewarded for their trouble

On Tuesday afternoon the members of the Congress were invited to an At Home at Apsley House on the invitation of the Duchess of Wellington. The gathering was a great success and the magnificent pictures were thoroughly admired.

On Tuesday evening the delegates and members of the British Congress on Tuberculosis were received at the Mansion House by the Lord Mayor and Lady Mayoress The spacious reception rooms were crowded—over-crowded in fact—with guests of all nationalities Herr Wurm's string band was delightful

On Wednesday afternoon the ladies of the Reception Committee entertained the delegates and members of the British Congress on Tuberculosis at a garden party in the Royal Botanical Gardens Regent's Park. The band of the 2nd Life Guards played selections during the afternoon as did also the Blue Hungarian Band, and Clifford Essex's Pierrots gave one of their well known entertainments The rain fortunately held off, though the sky was threatening

Professor R. Koch was entertained to dinner at the Hotel Métropole on Wednesday evening by the Royal Institute of Public Health, the occasion being taken of presenting to the guest of the evening the Harben Gold Medal for 1900 Professor Koch replied in German to the toast of his health proposed by Dr W R Smith the President of the Institute. He said that he was happy to remember that the first to recognise his work in anthrax were his English colleagues

Sir James Crichton Browne in the course of a reply to the toast of The Tuberculosis Congress remarked that there would have to be an inquiry by Government into the question of tuberculous infection from animal to man to settle the accuracy of Professor Koch's views If a Government Commission were formed he had been authorised by Sir James Blyth to offer that gentleman's model farm in Essex for the investigation

COMPLIMENTARY DINNER TO SURGEON-GENERAL J JAMESON, C B

IN the Grand Hall of the Hotel Cecil on July 24th a complimentary dinner was given to Surgeon General J Jameson C B when Sir William Church Bart (President of the Royal College of Physicians of London) presided Covers were laid for some 160 hosts of Surgeon General Jameson and the gathering was a very representative one

After the Royal toasts had been duly honoured

The CHAIRMAN proposed 'Our Guest He said that they had met from a desire to do honour to one who had deserved well both of his profession and of his country Surgeon General Jameson had had an active and varied life and entered the Army Medical Service so long ago as 1857 He attained distinction in the part he took in repelling the Fenian raiders in Canada and subsequently was engaged in fighting a severe epidemic of 'yellow jack in Trinidad For these services he received promotion and special thanks He had also done splendid work in the Franco German war and had served his country well in various parts of the empire. In 1896 he was appointed Director General of the Army Medical Department. The present war which they had good hopes was now coming to a close was a perfectly unique war unprecedented in its character and difficulties Never before had they had to meet such a foe The labours and difficulties which the Director General had had to surmount in this connexion were enormous and he had practically been in the position of the Israelites of old who had to make bricks without straw The actual organisation of the hospital service had to be done in South Africa and its success was in a large measure due to the rapidity and continuity with which Surgeon General Jameson was able to supply the *matériel* and *personnel* A few weeks ago Surgeon General Jameson in that room told them of the requirement that had been made upon him and that he had been able to meet them That was strictly accurate and the highest possible credit was due to him and to his department They all recognised the value of his long life spent in the service of the country and still more the constancy with which he stuck to his post and his work. They also wished to acknowledge the exceedingly able manner in which he kept up a good relationship between his own corps and their civilian brethren They wished him long life and strength that he might long enjoy the leisure which now had befallen him

Surgeon General JAMESON said that he felt some difficulty in replying to the toast and adequately expressing his feelings of profound gratitude to the medical profession for the compliment which they had paid to him and through him to the Royal Army Medical Corps It had been his fortune to be director general through a very eventful period when a strain had been put upon his department such as it never had to bear before In the early months of the war the whole of the establishment was expended and events developed so rapidly that the army was first doubled and then increased threefold With every unit that embarked medical *materiel* and *personnel* had to be provided and the demands were made upon a department which was already impoverished Up to the present time they had received 50 000 invalids from South Africa India, and the colonies since the beginning of the war They were all received and handled by his department, and he was ably assisted by the quartermaster-general's department. None of the patients were transferred to a civil hospital, and only those who were sick while on furlough gained access to civil hospitals. From the first to the last the work was done without a single hitch. His critics had asked how all this could be done and he would tell them how the "miracle" had been performed. First of all the Army Medical Reserve were called out and wherever possible men were enlisted and trained for the work. Then every man that could be spared from colonial stations was employed and he had been enabled to send out nearly 7000 trained men. The Militia Medical Staff Corps was also called upon and supplied 500 men, while the volunteers furnished 600 men. Pensioners were also invited to return to the colours and the invitation was well responded to. Outside his own corps the most useful was the St. John Ambulance Brigade, which gave them 1900 men, who for the most part had had no previous hospital training, but who soon made very efficient nurses. There was some difficulty in getting trained men at the beginning of the war but that was not the fault of the director-general or of the officers associated with him. They had for a considerable time urged the necessity of increasing the *personnel* but for the most part without avail. Then female nurses were employed and 800 were sent out. It was to the Queen and to the Princess Christian that they were indebted for being able to send out so many female nurses. The scheme arranged in time of peace with the Commander-in-chief did not include female nurses, and hence they were not sent out earlier in the war. The army nursing reserves had been of the greatest advantage and the nurses whom the Princess Christian had selected had rendered most efficient services even at the sacrifice of their lives, and the failures can be counted on the fingers of one hand. As professional men and taxpayers they might be interested to know something of what was done with regard to medicine and *matériel*. The medical vote was, in round numbers, £300,000, but £1,000,000 had been spent. The amount of this *matériel* sent to South Africa was 4000 tons. 151 staff and regimental units had been mobilised, 19 bearer companies formed, 28 field hospitals, five stationary hospitals, and 16 general hospitals had been prepared, as well as three advance and two base depôts for medicines. In this country two hospital ships were equipped and three hospital trains. Men and *matériel* were also sent out to enable the principal medical officer to organise many more units in South Africa. At the same time a large quantity of *matériel* had to be sent out for the China field force. From a recent report it was shown that at the present time there were 21,000 beds equipped, not counting the provision made for field hospitals. The private hospitals organised in this country were of the greatest service, and the country owed those who equipped them a deep debt of gratitude. He would point out to his critics that with regard to supply the medical department was only responsible for medicine and medical and surgical appliances. Food and so-called medical comforts were supplied on requisition to the Army Service Corps. Blame should be apportioned, therefore, to those who were in fault. With respect to ambulance arrangements, in view of the fact that the post of sanitary officer had been abolished against the advice of the medical department blame should be laid elsewhere than at the door of the Army Medical Department. As to the selection of sites for hospitals in camps that was the duty of the Royal Engineers or of the Barrack Department, but, as far as he was aware, those departments had not carried out that duty and the medical department had to undertake the alteration of buildings for hospitals at a time when every officer should have been employed in his own legitimate work. If in the future war was to be carried on on humanitarian principles it would be necessary for the medical department to obtain a large increase of transport. He had received many flattering reports from general officers of the work that had been done, but the medical department was not on an equality with the other departments. The Director-General was not a member of the War Office council over which the Secretary of State presided, or of the Army Board presided over by the Commander-in-chief, and it had happened that matters relating to his department had been discussed in his absence and he had not known of the decisions till after considerable delay. During the war no general had done better than Sir Redvers Buller, and he had spoken in high praise of the work of the medical department. Taking everything into consideration he was sure that in no war had the sick and wounded been so well looked after as they had been in the present one. When the history of the war was written he was convinced that that would be the verdict.

Sir WILLIAM MAC CORMAC, Bart., K.C.B., in proposing the toast "The Public Medical Services," said it was an unfortunate state of things, if he had been rightly informed, that at the present time there was not a single candidate applying for admission to His Majesty's medical service. In the work of the Medical Department in South Africa they had had some things to criticise, but many things to commend, and he was surprised that there were not more things with which to find fault. They had heard from the Director-General how his department had overcome the difficulties, and they had not only done their best, but that best had been extremely good. No one who had not been in the country itself could know of the difficulties under which the medical department had laboured. They had been blamed for that for which those in other departments were responsible, and it was somewhat strange that the Government had allowed Surgeon-General Jameson to leave the army without the customary recognition given to every one of his predecessors and without one word of thanks or acknowledgment.

Sir JOSEPH FAYRER, Bart., K.C.S.I., responded, and the toast of "The Chairman" proposed by Sir THOMAS GALLWEY, K.C.M.G., and briefly acknowledged by Sir WILLIAM CHURCH, brought to a close a very successful and notable evening.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The University of Birmingham.

THE first graduation ceremony of the new University was held in the Town Hall on July 7th. The Chancellor, the Right Hon. Joseph Chamberlain, took his place surrounded by a large array of graduates in full academic costume. A procession was formed from Mason College, the present seat of the University, to the Town Hall, where amid much enthusiasm the degree congregation was held. The students took a prominent part on the occasion, enlivening the proceedings by songs, observations on the candidates, and the exhibition of humour licensed for the time being. Mr. Chamberlain delivered an important speech on the attributes of an ideal university and laid down definite requirements to insure its success. An appeal for more funds accompanied the views that he expressed and he hoped that the lines laid down for future progress would be realised to the full extent. The proposal previously made that a rate should be levied for the University at one halfpenny in the pound was assented to at a subsequent meeting of the Town Council; this opens a fresh source of steady income which it is estimated will bring in £5000 a year—a valuable addition to the funds of the University. This has been adopted on the precedent of other towns and represents a certain income outside the voluntary efforts which have been so generously made by a large number of donors.

Birmingham and Midland Eye Hospital.

The annual meeting of the friends and supporters of this institution was held on July 15th, the seventy-first report being read. The subscriptions for the year amounted to £3961, an increase of £245 as compared with the previous year. The total number of patients treated were: in-patients, 1093; out-patients, 25,572. The medical report showed that 774 operations had been performed on in-patients, including 327 for the removal of cataract in its various forms, and of these only four proved unsuccessful. The operations necessitated the administration of anæsthetics in 194 cases. One patient died from the effects of chloroform, an accident which had not previously occurred in the hospital for 28 years. One difficulty had been experienced by the committee, that of obtaining a resident house surgeon—a circumstance attributed to the war in South Africa demanding the help of members of this class of the profession. The usual votes of thanks were passed.

Death under Chloroform.

A death under chloroform recently occurred at the Hospital for Women. The patient, aged 53 years, was undergoing an operation for cancer. Chloroform and ether were given. Professor J. T. J. Morrison found signs of pleurisy and said that the muscles of the heart were thin and of poor tone "Death from misadventure" was the verdict returned

Proposed West African Health and Sanitation Commission; Major Ronald Ross, F R S, late I M S, at Freetown

MR. ALFRED L. JONES presided on July 10th over a representative conference convened by the African trade section of the Liverpool Chamber of Commerce to consider the arrangements for carrying into effect the proposals of the Secretary of State for the Colonies, whether it should be recommended that the proposed West African health and sanitation commission should be appointed to proceed to each of the colonies separately or whether one commission should be appointed to proced to the whole of the colonies The following gentlemen were nominated to represent the commercial interests of the three chambers concerned —viz., Mr O. Tambacci for Liverpool, Mr Thomas Welsh for Manchester, and Mr J H Batty for London The month of October was suggested as a suitable time for the commission to leave England The nomination of a scientific expert, which had been suggested by Mr Chamberlain was next considered and it was unanimously agreed to nominate Major Ronald Ross, F R S, late I M S, to the post It was also suggested that a sanitary engineer should be appointed, and it was resolved that this suggestion should be communicated to Mr Chamberlain who should be asked to consent to this addition to the commission —A telegram was received on July 19th by the honorary secretary of the Liverpool School of Tropical Medicine from Major Ross, Freetown, Sierra Leone, to the effect that an active general crusade had been commenced by the expedition against mosquitoes at Freetown and that the progress was very rapid. Major Ross was employing 30 native assistants and would shortly depart for Lagos Major Ross gave a lecture on the "Malarial Mosquito" at Freetown on July 18th. The hall was crowded and much enthusiasm was displayed —At a meeting of the School of Tropical Medicine, held on July 22nd, a letter was read from Major Ross stating that before any practical anti mosquito measures could be taken at Bathurst, Gambier, it would be necessary to make careful inquiries there to ascertain the source of the mosquitoes, the danger of malaria among native children, and the most feasible steps for dealing with the insects He therefore recommended that someone should be sent out for this purpose The school unanimously resolved to adopt Major Ross's advice and arrangements are now being made for the despatch of another expedition to West Africa, making in all the seventh sent out by this enterprising school.

Death of the Medical Officer of Health of Warrington

The death of Mr J H Gornall, the medical officer of health of the borough of Warrington, took place on July 18th after a somewhat prolonged illness The deceased was a native of Preston and was 59 years of age. In 1857 he was apprenticed to his uncle, the late Mr. Kenyon of Wavertree, and four years later he entered as a student at [the school of medicine of the Liverpool Royal Infirmary He obtained the Membership of the Royal College of Surgeons of England and the L S A. in 1864 He retired from private practice in 1880 upon his appointment as medical officer of health of Warrington He also held the posts of public analyst and medical superintendent of the Warrington Fever Hospital and was appointed a justice of the peace in 1885 The late Mr Gornall was universally esteemed His eldest son, Dr J G Gornall, was recently appointed deputy medical officer of health of the borough of Warrington.

Distribution of the Hospital Saturday and Sunday Fund

The committee of the Hospital Saturday and Sunday Fund have allocated £13,365 among the various hospitals of the city. This is the largest amount ever distributed in the history of the Fund. The Royal Infirmary received £2943, the Royal Southern Hospital £2010, the David Lewis Northern Hospital £1742, and the Stanley Hospital £1138 Other charities received contributions in proportion to the number of beds available.

Cricket Match between Manchester and Liverpool Medical Men.

On July 16th the annual cricket match between Liverpool and Manchester medical men took place at Aigburth, in glorious summer weather, in the presence of a fashionable company Liverpool came off victorious

Important Defence in a Meat Prosecution

A BUTCHER was charged at the Swansea police court on July 9th with having in his possession a forequarter of beef which was unfit for the food of man The meat had been seized by the meat inspector who is a qualified veterinary surgeon, and the defendant's solicitor at the commencement of the hearing claimed that the medical officer of health and the inspector of nuisances were alone competent to make the seizure The presiding magistrate upheld this contention, but consented to hear the case and if desired to state a case for a superior court The proceedings occupied the greater portion of two days and on July 18th a fine of £2 with costs amounting to £20 5*s* was imposed In giving his decision the magistrate stated that he now thought that it was competent for the meat inspector to make the seizure An appeal to quarter sessions will probably be made

Gynæcologist to Cardiff Infirmary

Dr Ewen John MacLean was on July 17th elected gynæcologist to the Cardiff Infirmary in succession to the late Dr. John D Williams There were six candidates for the appointment, three of whom were medical practitioners residing in Cardiff

A Prescribing Druggist Fined

A druggist named Jenkins was fined £20 at the Carmarthen county court on July 18th for practising as an apothecary without having a licence of the Society of Apothecaries In the course of the proceedings the coroner for West Carmarthenshire stated that Jenkins had appeared before him on four different occasions when inquests had been held upon persons who had been prescribed for by the defendant The defence raised was that the medicine was alone charged for and not the advice

Swansea Convalescent Home

The anonymous donor of £500 dowards the erection of a convalescent home in connexion with the Swansea Hospital and who, as stated in THE LANCET of July 20th p 174, had raised the amount to £5000, has still further increased it to £10,000 The building, which it is estimated will cost £12,000, will be proceeded with at once

Outbreak of Diphtheria at Keynsham

Early in July an outbreak of diphtheria occurred at Keynsham, a rural district with a population at the last census of 8266 persons adjoining Bristol In a report to the district council Mr J C Heaven, the medical officer of health, states that upon visiting the school which was attended by the child who was first attacked he saw 12 pupils apparently quite well, but who were found, after bacteriological examination of material taken from their throats had been made to be suffering from the disease. Altogether 29 persons were attacked, of whom 16 were removed to the isolation hospital

The Hughes Bennett Laboratory of Physiology at Edinburgh.

ON July 20th the new physiological laboratory which has been built by Mrs Cox widow of the late Mr Robert Cox, M P, of Gorgie, in memory of her father, Professor Hughes Bennett of Edinburgh University, was opened and formally handed over to the university authorities by the donor. The inaugural ceremony took place in the new laboratory, Principal Sir William Muir presiding There was a large gathering of ladies and gentlemen, including members of the professoriate and university bodies and many eminent physiologists from various parts of the kingdom After apologies for absence had been read by Professor E. A. Schäfer, Mrs Cox, in handing over the laboratory, addressed the Vice-Chancellor as follows:—"I ask you, on behalf of the university, to accept this laboratory which I have built to the memory of my dear father and to help physiological research in the university." Sir William Muir thanked Mrs. Cox in the name of the university for the great work which she had done for the university in building the new laboratory and in dedicating it to the memory of her father, Professor Hughes Bennett. Mrs. Cox then unveiled a bronze bas-relief representation of her father which is fixed to the south wall of the largest room in the laboratory. Sir John Burdon Sanderson, Bart., F.R.S., Regius Professor of Medicine in the University of Oxford, then expressed on behalf of the students of Professor Hughes Bennett who were present their high appreciation of the exactitude of the likeness which the sculptor, Mr. Macgillivray, had given them. The bronze panel presents the figure in half-length with the face three-quarters to the left. The figure is seated, the left arm lying on the arm of a chair. The inscription below it runs as follows:—"John Hughes Bennett, M.D., F.R.S.E., Professor of the Institutes of Medicine and of Clinical Medicine in the University of Edinburgh. The first in this country to teach the use of the microscope in the clinical investigation of disease. This laboratory was erected as a memorial by his daughter in 1901." The company then adjourned to the McEwan Hall, where Sir John Burdon Sanderson delivered an address on the life and work of Professor Hughes Bennett. In this address Sir John Burdon Sanderson in the first place gave a sketch of Professor Hughes Bennett's career as a student. He then described his work as an extra-academical teacher and as a professor, and spoke of the influence which he exerted on the men who began their training as practitioners under him, referring finally to the special service which he had rendered to the science of medicine in this country in combating the use of antiphlogistics and bleeding in acute disease. Professor J. G. McKendrick proposed a vote of thanks to Sir John Burdon Sanderson, which was seconded by Sir John Batty Tuke, M.P. Sir William Muir, in closing the proceedings, again expressed the indebtedness of the university to Mrs. Cox for her munificence. The laboratory is in direct connexion with the existing laboratories. It consists of a large laboratory for practical work by individual students and a small theatre intended specially for demonstrations of experiments by the professor. This theatre will accommodate from 90 to 100 students. It will have an electric lantern. Part of the large laboratory has been partitioned off to provide, in the meantime, a room for microscopic demonstrations.

(FROM OUR OWN CORRESPONDENTS.)

The Sanitary Condition of Whitehouse.

DR. C J. CLIBEORN, Local Government Board medical inspector, reports in reference to the Whitehouse districts in the neighbourhood of Belfast that there is no regular inspection of the meat- and milk-supplies and that the sewerage of Upper and Lower Whitehouse is not sufficient or satisfactory. Typhoid fever has been prevalent in the Upper Whitehouse district, and although the subject of the sewerage of Upper Whitehouse has been under consideration for years nothing has been done. It is to be hoped, the inspector writes, that the district council will without further delay perform this necessary work. The Infectious Diseases (Notification and Prevention) Acts have not been adopted, and it is recommended that the district council should adopt both these Acts.

North of Ireland Branch of the British Medical Association.

The twenty-third annual meeting of the members of the North of Ireland Branch of the British Medical Association was held in the Museum, Belfast, on July 18th, the President, Professor J. W. Byers, being in the chair. After the minutes had been read the annual report and statement of accounts were submitted and passed. There are now over 300 members and the branch is the largest in Ireland. The work during the past year was excellent and there is now a balance in hand of over £20. Dr J. S. Darling (Lurgan) was elected president for the ensuing year, Dr. John Campbell and Dr. D. P. Gaussen were chosen as vice-presidents, Dr George Gray (Newcastle) was elected treasurer, and Dr. W Calwell secretary. Professor Byers and D. Calwell were elected representatives of the branch on the central council of the British Medical Association and Dr. Alexander Dempsey was elected on the Parliamentary Bills Committee. The following scientific work was then brought before the meeting. Dr. T. S. Kirk read notes of a case of Suppurative Nephritis treated by Nephrotomy and showed two cases of Excision of the Hip; Dr. A. B. Mitchell gave a lantern demonstration illustrative of the Conditions Found and Different Operations carried out in a Series of 18 Operations on the Stomach; Dr. C. E. Shaw gave brief notes of the removal of an Ivory Exostosis from the Auditory Meatus; Professor W. Whitla showed a specimen of a Dissecting Aneurysm; Dr. R. J. Johnstone showed specimens of Charcot's Joint Disease, Endothelioma of the Ovary, Sarcoma of the Ovary invading the Myoma of the Uterus, and Healed Typhoid and Dysenteric Ulcers; and Dr. Dempsey showed a Fibroid Tumour of the Uterus removed by Retro-peritoneal Hysterectomy. After the meeting Professor Byers entertained the members at luncheon in the Prince's Restaurant. The President gave the toasts of the King and the City of Belfast, to which the Lord Mayor (Sir Daniel Dixon, D.L.) responded. Mr. G. L. St. George, J.P., in a very happy manner proposed the health of the President (Professor Byers), to which that gentleman responded, and spoke of the great services rendered to the branch by the very efficient secretary, Dr. Calwell, who, most unwillingly, owing to an assize case, was unable to be present.

The Typhoid Fever Epidemic in Belfast.

In reply to the report issued by the Public Health Committee blaming the water-supply at Stoneyford as the cause of the outbreak of typhoid fever the Water Commissioners have promptly, through their chairman, shown that there is another side to the question. Attention is drawn to the fact that, although the defective nature of the drains in many of the houses affected in the district where the present outbreak occurred and the insanitary condition of many of the dwellings and inmates are admitted yet no importance is attached to these serious elements and vital causes of typhoid fever. The reporters visited Stoneyford in June last and being informed that two cases of typhoid fever had occurred in farmhouses as far back as Feb. 5th and 28th they concluded without further inquiry that the Stoneyford water caused the outbreak in Belfast in May and June last. The Water Commissioners reply that the houses were thoroughly disinfected and all the manure and excreta from the patients were completely removed by their employés to lands outside the catchment area and that not a drop of water from this area was admitted into the Stoneyford reservoir from Dec. 23rd 1900, until March 21st of this year—that is, for a period of eight weeks prior to the occurrence of the typhoid fever in this area and some four or five weeks after. Further, no reference is made to the effect of the prolonged storage to which the water is subjected in the reservoirs or to the after-treatment of the water at the filters which have been found to reduce 99 per cent. of the bacteria. It is asked, further, why, if the Stoneyford water was the cause of the present outbreak, do Dunmurry and all the high levels of the city of Belfast from the Upper Falls to the Crumlin-road and Old Park-road, which are supplied by the same water, escape. The commissioners were uninformed of the visit to their catchment area of the gentlemen who drew up the report for the Public Health Committee; had they been informed of it they would have told them of the important precautions taken by them to prevent any pollution of the catchment area. In a word, this report of the Water Commissioners implies that it is the bad sanitary condition of the district where the typhoid fever first appeared which is the real cause of the epidemic and not the water, which had it been infected with typhoid germs would have caused an outbreak in the whole area supplied by it. It is satisfactory to know that last week the cases of typhoid fever had fallen to 79. It is thought that the corporation will demand a Local Government Board inquiry into the causes of the epidemic.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Treatment of Puerperal Infection.

AT the meeting of the Academy of Medicine held on July 9th M. Budin gave a descrip the method of

treating puerperal infection as used by him since 1892. In the normal puerperium involution of the uterus takes place quickly, so that after a few days the internal os is closed. But if the uterine mucosa has been infected the underlying muscular fibres are paralysed and there is no difficulty in passing the finger into the uterine cavity. This abnormal permeability of the uterus is of great importance from a diagnostic point of view. For thorough cleansing the patient must be deeply anæsthetised and the uterus curetted with the finger. The cavity must also be mopped out with fairly large swabs. Facts go to show that the cleansing of the interior of the uterus can be very thorough. According to M. Budin if fever supervene in a woman recently confined and clots are found in the uterus they should be removed whether stinking or not, and if this is followed by washing out the uterus possibly sufficient will have been done. If, however, the uterine mucosa is infected, especially at the placental site, digital curetting and swabbing must be carried out. Recovery is generally rapid if treatment has been entered upon at an early stage. If the infection has lasted for some days recovery is very slow, for both the germs and their toxins have entered the system. Recovery has been known to occur even in apparently desperate cases, but death sometimes supervenes. Another consequence results from these facts—i.e., should a woman be confined or should she abort, if [illegible]
since th [illegible]
swabbing [illegible]
prophylactic measure (*nettoyage prophylactique*). At the Tarnier clinic there are some isolation beds into which women are taken who have become infected either outside the hospital or within its walls. During the last academic year, from Nov. 1st, 1900, to June 30th, 1901, 33 infected patients were admitted from outside. In four of these cases uterine injections after digital exploration resulted in recovery. In 13 cases *nettoyage prophylactique* was performed and in 16 digital curetting and swabbing were done. Only one woman succumbed who had come in from Choisy-le-Roi in a desperate condition eight days after her confinement. Of patients already in the hospital 59 became infected and were sent to the isolation wards. All recovered. The total number of cases for the term was 1137 confinements or abortions taking place in the clinic with no deaths from infection. M. Budin, while allowing that the death-rate for the term under review was exceptionally light, considers that his methods have a great deal to recommend them.

On a Micro-organism found in Syphilitic Plasma.

M. Jullien not long ago stated before the Academy of Medicine that in the blood and serum of syphilitic patients who had recently been infected and who had not undergone any specific treatment M. de Lisle and himself have confirmed the presence of round granular highly refracting bodies such as have been already described by other observers. M. Jullien and M. de Lisle have, however, been unsuccessful in cultivation and inoculation experiments with these granules. This is not surprising, for it is well known that syphilitic blood when once coagulated is harmless, a peculiarity which may be explained by the existence in the blood after coagulation—i.e. in the serum—of an "alexine" which is strongly bactericidal. Researches have also been undertaken into the nature of the serum from a blister, whether produced by cantharides or by the actual cautery. Such serum M. Jullien and M. de Lisle found to contain no alexine whatever. They did find, however, a polymorphic organism bacillary in shape and showing all intermediate stages between that of a slender rod (from 5 μ to 8 μ in length and from 0·15 μ to 0·30 μ in breadth) and that of a long filament. The organism was mobile, staining easily with the usual reagents but not by Gram's method. It caused bouillon to become turbid in 24 hours, forming a thick growth thereon in from four to five days. It liquefied gelatine and grew well on glycerin, also on potato, amniotic fluid, gelose, and solidified serum. It would grow under anaerobic conditions but only slowly. As the age of the culture increased the appearance of the microbe altered so that after 10 days or so nothing was seen but the granules which had been originally observed in the blood of syphilitic patients. If a re-culture was made the primitive characters reappeared. After 30 days the cultures were apparently dead, but could be revived by appropriate measures. If these organisms were injected into the peritoneal cavity of a guinea-pig there resulted paralysis, wasting, abortion, and death in from 10 to 15 days. Young animals died in 12 hours. Subcutaneous inoculation brought about an indurated area which afterwards ulcerated, while the glands in the vicinity swelled up. On post-mortem examination the blood was always found to be sterile. In syphilitic patients inoculation was unsuccessful whether through an open wound or by absorption. The specificity of this pathogenic organism appears evident from two facts—firstly, it is agglutinated by the serum of patients obviously suffering from syphilis; an agglutination which does not occur with the serum of healthy patients, and secondly, the property which it possesses of being acted on by the alexine contained in the serum of animals which have been inoculated with syphilitic poison—a fact which proves the existence of specific properties.

July 23rd.

CANADA.

(FROM OUR OWN CORRESPONDENT.)

Ontario Medical Association.

THE twenty-first annual meeting of the Ontario Medical Association was held in Toronto on June 19th and 20th under the presidency of Dr. Angus McKinnon (Guelph). Dr. William Oldright, Professor of Hygiene in the University of Toronto, reported on three recent gall-stone cases; in these cases two patients were operated on successfully and an uneventful recovery was noted. The third case was found to be complicated with malignant disease on opening the abdomen. Had the patient been operated on a few years before Dr. Oldright thought that her life might have been saved. It was impossible to locate the gall-bladder in this case. Dr. Herbert A. Bruce (Toronto) showed a woman, 34 years of age, from whom he had removed the left upper jaw for sarcoma. The disease was first noticed as a swelling, slight in character, simulating a gum-boil on the alveolus of the left upper jaw. Dr. Silverthorn presented the pathological specimen and stated that it contained spindle cells with a cartilaginous basis. It was as large as a good-sized orange. A very interesting discussion took place on Ectopic Gestation which was introduced by Dr. R. W. Garrett, Professor of Medicine in Queen's University, Kingston, Ontario. He directed attention to arrest within the tube or tubal pregnancy principally, and thought that in a fairly large proportion of these cases a diagnosis ought to be made before the occurrence of rupture; every physician should be able to make the diagnosis after the occurrence of rupture. Dr. J. F. W. Ross thought that they should now be able to make these cases out before the rupture took place. At the opening of the afternoon session the President delivered the annual address. It was practical and thoughtful and dealt with the "fakes" in medicine, or rather those which hang on to the skirts of medicine. The Dowieites, the Christian Scientists, the electric-belt men, and the pray-for-hire healers, as well as their advertisements in the daily press and also in the religious papers were condemned most freely. Dr. McKinnon further deprecated manufacturers making up pills for neuralgia, &c. There should also be better facilities for getting the subjects of acute mania into asylums, so as to avoid irritating delays. Dr. P. H. Bryce, Secretary of the Ontario Board of Health, read a practical paper on the vaccinal protection against small-pox which, in view of the fact that this disease has been, and is still, prevalent throughout the province, evoked animated discussion. He considered that there never was a time since the introduction of vaccination when there was so much carelessness in regard to it amongst the laity as well as amongst the profession. Dean Geikie of Trinity Medical College considered Jenner's discovery to be one of the grandest and most glorious in the annals of medicine. A special committee, on the suggestion of Dr. Wishart, drew up a motion, which was subsequently passed, approving of from three to five insertions in the practice of vaccination and calling upon the profession to be more diligent in the performance of this art. Mr. I. H. Cameron warned the profession against laxity in dealing with this most important subject. Empyema was another question which evoked a very interesting discussion. In a carefully prepared paper, it was introduced by Dr. R. Ferguson (London, Ontario) who confined his remarks to the medical aspect of it. Dr. J. L. Turnbull (Goderich) dealt with the surgical side of the question, stating that it was his practice when pus was present to take out a portion of a rib about one and a half inches in length. Particular attention should always be paid to the hard fibrous tissue which was always present beneath the ribs. The Open-air Treatment of Disease was the subject of a paper by Dr. George H. Carveth (Toronto), who described his method of treating diseases, firstly in rooms with wide-open windows; secondly, on verandahs; and, thirdly, in tents on the lawns. Some of the cases which he had treated in this way were iritis, cases of fracture, cases of the radical cure of hernia, rheumatoid arthritis, tuberculous disease of the spine, typhoid fever, and a case of hysterectomy. When once accustomed to open-air life there was great difficulty in getting patients to return indoors. Dr. L. Coyteux Prevost (Ottawa) read a lengthy paper on the Use of Nitrous Oxide and Ether as an anæsthetic. The Complications and Degenerations of Fibroid Tumours of the Uterus with reference to the treatment of these growths was a subject ably dealt with by Dr. Charles Noble (Philadelphia). Dr. Arthur Mayburry (Toronto) contributed a paper on the Relation of Nasal Obstruction to Obscure Cases of Asthma; while Dr. J. T. Duncan (Toronto) read a paper on the Importance of an Early Recognition of Locomotor Ataxia. He referred chiefly to the eye symptoms as aids to an early diagnosis. Dr. D. J. Gibb Wishart spoke on the use of adrenalin which he had found very useful as a hæmostatic in many cases. He considered it to be a valuable adjunct to the medical man's armamentarium. Another important discussion took place on Gastric Ulcer. Dr. R. D. Rudolf (Toronto) opened this discussion, speaking of the relation of cancer to ulcer, the value of ergot, the question of diagnosing the site of the ulcer, and whether cases of apparently "cured" gastric ulcer are "first-class lives" for insurance. Dr. H. B. Anderson, Pathologist to Trinity Medical College, dealt with the pathological aspect lucidly, while Dr. Henry Howitt contributed an exhaustive paper on the surgical aspect. In distension it was Dr. Hewitt's practice to evacuate the bowels. One or more small incisions in the prominent coils soon overcame the distension and each one was closed before another was made. "On the Relation of Hyperacidity of the Stomach to Bilious Attacks, some Forms of Eczema, Muscular Rheumatism, and Gout," was the title of a paper contributed by Dr. Graham Chambers (Toronto) and it exhibited careful observation on the part of the writer. In the medical treatment of surgical tuberculosis Dr. W. B. Thistle (Toronto) thought that in surgical tuberculosis the medical treatment was too often neglected and that cases would do better if medical treatment were added to the surgical. Dr. Walter McKeown (Toronto) dealt with the treatment of Post-operative Peritonitis. A committee was appointed to report on the propriety of establishing a medical defence union in Ontario; and a resolution was unanimously passed upholding the action of the Ontario Medical Council in enforcing payment of the annual $2.00 assessment. The following were the officers elected: President, Dr. N. A. Powell (Toronto); first vice-president, Dr. R. Ferguson (London, Ontario); second vice-president, Dr. R. W. Garrett (Kingston); third vice-president, Dr. L. C. Prevost (Ottawa); general secretary, Dr. Harold C. Parsons (Toronto); assistant secretary, Dr. George Elliott (Toronto); treasurer, Dr. A. R. Gordon (Toronto). Toronto was selected as the next place of meeting.

(FROM OUR OWN CORRESPONDENT.)

Passengers' Rights on Electric Street Cars.

ACCIDENTS due to the haste of conductors are of almost daily occurrence on street cars. However expeditious in his movements the passenger may be he is constantly ordered by the conductor to "hurry up" or to "step lively," whether he be leaving or entering a car. The cause of the accident is generally the starting of the car before the passenger is safely on or off, as the case may be. Generally he has grasped the handle of the car lest he should fall and he clings to it, being dragged along, in his effort to recover his footing. The courts put a liberal construction upon the rights of passengers on these cars. In a recent case a man sued the Street Railway Company for injuries received while trying to board one of their cars. He had grasped the handrail and waited for other passengers to enter the car; the start was made with a jerk and he was only partially on the car, having his left foot on the step. He was thrown off, but ran along side of the car, endeavouring to board it, when he was hit by a projection in the street hiding a hole in the pavement; this blow threw him into the hole. His suit was at first dismissed, but on appeal the first decision was pronounced to be an error and the court held that the defendant was bound to give the plaintiff time to board the car, and the evidence proved that reasonable time was not allowed and that in this respect the defendant was negligent. The court held that the plaintiff was not guilty of contributory negligence; having hold of the car and being about to board it, it suddenly started, thereby presenting an emergency which required the exercise of judgment as to the best course to be followed to prevent injury. If to avoid being thrown down by the car he held on to the rail to steady himself until he could let go in safety it was certainly not negligence as a matter of law. But for the existence of this trench in the roadway alongside of the track, which he had not observed, he would probably have escaped injury by adopting the course which he did, but his falling into the trench was caused by his being dragged along by the car. It seemed to the court that the question of contributory negligence was one for the jury. If the car had not started the plaintiff could have got aboard safely. It, however, started when he had hold of the car and the sudden jerk carried him along with it, and if he, to avoid falling, kept hold of the car until he could regain his equilibrium, and in so doing was by the momentum of the car thrown into this trench, it was the sudden starting of the car and the motion contributed by the car to the plaintiff which caused him to fall into the trench from which he sustained the injury for which he sought to recover.

Foreign Relations of the American Medical Association.

It appears from the address of the President of the American Medical Association, Dr. C. A. Reed, that this society had accredited delegates during the last year to several foreign medical conventions, notably the International Medical Congress at Paris, the Dominion Medical Association of Canada, the Mexican National Association, and the Pan-American Medical Congress at Havana. With each of these organisations the American Medical Association sustains relations of peculiar intimacy. As one of the great scientific nations of the earth the United States is naturally an integral part of the International Medical Congress. This association by resolution presented by its present president, took the initiative in 1891 in organising the Pan-American Medical Congress. The first réunion of that Congress was held in Washington in 1893 under the presidency of the late lamented Dr. Pepper; the second was held in the city of Mexico in 1896 under the presidency of Dr. Carmona y Valle; and the third was convened during the last few months in the city of Havana under the distinguished president, Dr. Juan Santos Fernandez. The object of this movement is the establishment of closer relations between the medical profession of the different countries of the Western Hemisphere. Excellent fruit has already been borne in the increased patronage of our medical schools from the far South; in the improved status of American medical practitioners in Latin America; in the better understanding of quarantine questions in the different countries; and in the development of concerted action in the investigation of the medical flora of the Western Hemisphere.

A National Pharmaceutical Laboratory.

The movement for a memorial fittingly to perpetuate the name of William Proctor, jun., was started some months ago by the American Pharmaceutical Association. Its growth has been vigorous and pharmacists in various parts of the country have become identified with the plan. William Proctor, jun., was one of the best-known pharmacists of his day, and by some persons now living he has been called the "Father of Pharmacy." Something will be done in the near future in memory of the results which he obtained in his efforts to enlarge the knowledge of pharmacy and to elevate the calling of the pharmacist. The present proposition is to establish a National Pharmaceutical Research Laboratory. If this should fail of realisation, the New York State Pharmaceutical Association, with which the project originated, would urge that the name of William Proctor, jun , should be perpetuated and be made widely known to future generations by founding scholarships bearing his name at colleges of pharmacy here, or that medals for conspicuously meritorious work in any of the branches of pharmacy should be given

July 18th

AUSTRALIA

(FROM OUR OWN CORRESPONDENT)

Outbreak of Small-pox

SOME time ago Western Australia altered the quarantine regulations of that State and relieved ships carrying surgeons from medical inspection, *pratique* being granted on the certificate of the ship's surgeon that there was no infectious disease on board In South Australia the chairman of the Board of Health, Dr Ramsay Smith is an advocate of surveillance, as opposed to strict quarantine, and is supported in his views by the Premier of the State The latter has communicated with the Federal Premier of Australia, stating that if the Commonwealth Government does not propose to take over the quarantine department for some time it will be *necessary to bring in an amending Quarantine Act in the* South Australian State Parliament, with this object in view Power to assume control of quarantine is conferred by the Constitution Act, but the transfer cannot be made till a date for handing over the quarantine stations has been fixed by the Commonwealth Parliament The New South Wales, Victorian, and Queensland authorities uphold strict quarantine but under their several Acts have no power to insist on the detention in quarantine, in the State, of a patient who prefers to go on in the vessel to the next port of call, but can only quarantine those of the passengers or crew who land The way these varying regulations work out in practice has been well exemplified recently The steamer *Chingta* arrived some six weeks ago at Thursday Island and was found to have a case of small pox on board The authorities then offered to take the patient off and to isolate him, but the captain decided to go on as he said the patient could be isolated on board The steamer went on to Sydney and was quarantined there and small pox broke out among the passengers and crew while in quarantine, one patient dying In the opinion of Dr Ashburton Thompson President of the Board of Health, these patients were all infected on the voyage between Thursday Island and Sydney, and if quarantine and isolation had been enforced at Thursday Island the outbreak would not have occurred More recently the Orient steamer *Ormuz* arrived at Fremantle and was reported free from infectious disease by the ship's surgeon but, in accordance with the regulations in West Australia, was not boarded or inspected by the port medical officer Free communication took place with the shore passengers landed and other passengers embarked for the eastern ports On reaching Adelaide the port medical officer boarded and was again informed that there was no infectious disease on board, but as strict precautions were being taken with regard to plague he proceeded to inspect the passengers and crew Having completed the inspection of the passengers he allowed the mails to go ashore and visitors to come on board While inspecting the crew he found a man sick and was told by the ship's surgeon that it was not an infectious case The port officer, however thought it was small pox, went ashore and got another opinion and the advice of the President of the Board of Health, and his opinion being confirmed ordered the ship and all on board into quarantine. The Adelaide passengers and visitors were landed at the quarantine station The *Ormuz* went on to Melbourne where the Melbourne passengers were quarantined, and the original patient was isolated at the sanatorium Then the ship went on to Sydney where the remaining passengers were quarantined When the Adelaide passengers had been 11 days in quarantine Dr Ramsay Smith advised that they should be released and kept under surveillance The Melbourne and Sydney authorities, however, objected and the very next day two cases of *small pox developed among the passengers quarantined* at Adelaide Meanwhile among those quarantined at Melbourne six cases of small pox developed, and among those quarantined in Sydney 19 cases one fatal One of the cases at Adelaide occurred in a passenger from Fremantle, so that here again the disease was caught on the voyage between the first Australian port, Fremantle, and the next port of call, and the whole outbreak, involving very heavy expense indeed, could have been avoided by proper measures at Fremantle Further, at Fremantle itself the policeman on duty on the *Ormuz* while there has been attacked with small pox In Sydney two cases of small pox have occurred among the general inhabitants who had no communication whatever with the infected vessels, but were probably infected from the *Chingta* cases and in Adelaide two of the residents who boarded the *Ormuz*—a newsboy and a constable—and were quarantined with the passengers have developed small pox Yet a third muddle has occurred still more recently When the R.M S *Arcadia* arrived at Adelaide the port officer carefully inspected the crew and discovered a steward with a suspicious rash , the diagnosis of small pox having been confirmed by a second expert opinion, though disputed by the ship's surgeon, the ship was quarantined Some of the Adelaide passengers elected to go on to Melbourne in the ship, others went to the quarantine station, already crowded with the passengers of the *Ormuz* On arrival at Melbourne the three experts of the Board of Health pronounced the case not to be small-pox and granted the vessel *pratique* The 40 Adelaide passengers who came on to Melbourne were then sent back and those who had been quarantined there and mixed with the *Ormuz* passengers were also released

Prince Alfred Hospital, Sydney

The foundation stone of the Queen Victoria Memorial wing of the Prince Alfred Hospital Sydney was laid on May 31st by H R.H the Duke of Cornwall with great *éclat* The Royal party were received by Professor Anderson Stuart, President of the hospital, who read an address giving a history of the hospital and detailing the work it had accomplished After the stone had been laid the Duke of Cornwall made the following speech "It is with deep satisfaction that the Duchess and I have taken part in this interesting ceremony , for in the first place I should like to hope that possibly our presence here to day may conduce even though in the smallest degree to the advancement of the splendid work which has already been accomplished by the Prince Alfred Hospital Then I am proud to think that whether I turn to the past history of the hospital or try to look into its future I find a close association with it and my family His Majesty the King is its patron *It found its birth in the* loyal outburst of thankfulness on the part of the people of New South Wales for the recovery of my dear uncle the Duke of Edinburgh from the result of a dangerous attack upon his life In the title Queen Victoria Memorial Pavilions which you have chosen for the new buildings, the foundation stone of which I have had the honour of laying to-day, you identify them for ever with the imperishable memory of our late dearly beloved Sovereign I doubt whether under the circumstances any more fitting memorial to that great life could have been chosen for sympathy with the suffering was an all pervading element in the noble and beautiful character of her who was your first patron and with whose name the hospital will now be associated for all time Another personal connexion exists in the fact that 20 years ago my dear brother and I visited the hospital then unopened, and that to-day I have been allowed to inaugurate what will be the completion of the originally conceived scheme Since that time the hospital thanks to excellent administration combined with a zealous and able staff has achieved results which have earned commendation from a competent hospital authority who spoke *of it as one of the best managed* institutions in the world As an example I merely mention that since it has been opened *in* 1883 *some* 188 000 people have received medical treatment from it either as in door or out door patients The rapidly growing population of your city brings an ever daily increased demand to such an establishment and it is hoped that these new additions will meet the further present requirements for greater accommodation I am glad to learn that thanks to the generosity of the public, the necessary funds are now almost guaranteed I feel confident that you will gladly join with me in offering hearty congratulations to Professor Anderson Stuart and his brother directors for such liberal support may be taken as a proof of *recognition* by the Government and the community at large of the inestimable benefits which have been conferred on your suffering *fellow creatures by the institution whose* direction was fortunately left in their hands "

June 22nd.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen having passed the necessary examinations have been admitted Fellows of the College in the order of their seniority as Members, and have received their diplomas:—

John Beuzeville Byles, diploma of Member dated Nov. 13th, 1891, M.B., B.C. Cantab., L.R.C.P. Lond., Westminster Hospital; Herbert William Kendall, Member, I [illegible] Hospital; James Keogh M [illegible] M.D., B.C. Cantab., L.R.C. [illegible] St. Bartholomew's Hospital; Robert Earle Newton, Member, July 29th, 1895, M.B., C.M. Glasg., L.R.C.P. Lond., Glasgow University and St. Bartholomew's Hospital; Cecil Banting, Member, Feb. 13th, 1896, M.D., B.S. Lond., L.R.C.P. Lond., University College and Guy's Hospitals; Philip Northcott Vellacott, Member, May 14th, 1896, M.B., B.S. Lond., L.R.C.P. Lond., Guy's Hospital; William Robert Gibson, Member, August 4th, 1896, L.R.C.P. Lond., St. Bartholomew's Hospital; Robert Pugh Rowlands, Member, August 4th, 1896, L.R.C.P. Lond., Guy's Hospital; Ferdinand Stanley Batchelor, Member, July 29th, 1897, L.R.C.P. Lond., Guy's Hospital; Howard Henry Congreve Dent, Member, July 29th, 1897, M.B. Durh., L.R.C.P. Lond., Durham University, Mason University College, Birmingham, and St. Bartholomew's Hospital; Joseph Faulkner Dobson, Member, July 29th, 1897, M.B., B.S. Lond., L.R.C.P. Lond., Yorkshire College and Gene [illegible] ancis Astley Cooper Tyrrell, Member, No [illegible] B.C. Cantab., L.R.C.P. Lond., Cambridge [illegible] and King's College Hospitals; Arthur Hyde Greg, Member, Feb. 10th, 1898, L.R.C.P. Lond., Cambridge University and St. Thomas's Hospital; George Ernest Gask, Member, August 2nd, 1898, L.R.C.P. Lond., St. Bartholomew's Hospital; William Halliburton McMullen, Member, Nov. 10th, 1898, M.B. Lond., L.R.C.P. Lond., King's College Hospital; William Howard Unwin, Member, Nov. 10th, 1898, M.B. Lond., L.R.C.P. Lond., University College and Charing Cross Hospital; Harold Shuttleworth Barwell, Member, Feb. 9th, 1899, L.R.C.P. Lond., St. George's Hospital; Harold Vaughan Pryce, Member, Feb. 9th, 1899, B.A. Cantab., L.R.C.P. Lond., Cambridge University and St. Bartholomew's Hospital; Harold Burrows, Member, May 11th, 1899, M.B. L.R.C.P. Lond., St. Bartholomew's Hospital; Graham Scales Simpson, Member, July 27th, 1899, L.R.C.P. Lond., L.D.S. Eng., Guy's Hospital; Herbert George Tymms, Member, Nov. 2nd, 1899, M.B., B.S. Melb., L.R.C.P. Lond., Melbourne University and St. Bartholomew's Hospital; William Henville Lowman, Member, May 10th, 1900, M.B., B.S. Lond., L.R.C.P. Lond., University College, Bristol, and King's College Hospital; Robert Young Aitken, Member, Feb. 7th, 1901, M.D. Glasg., L.R.C.P. Lond., Glasgow University; and Joseph Cunning, not a Member, M.B. Melb., Melbourne University and St. Bartholomew's Hospital.

Fifty-six candidates presented themselves for this examination, 25 of whom passed, one of whom not having attained the legal age of 25 years, will receive his diploma at a future meeting of the Council. 31 candidates were referred, 24 for six months and seven for 12 months.

UNIVERSITY OF LONDON.—At the Intermediate Examination in Medicine, held in July, the following candidates were successful:—

EXAMINATION FOR HONOURS.

Anatomy.—First Class: Seymour Gilbert Barling* (Deserving of Medal), Birmingham University; Ernest Edgar Maples (Gold Medal), St. Bartholomew's Hospital; William Gordon Taylor (Exhibition and Medal), Middlesex Hospital; and Edwin Robert Wheeler, King's College. *Second Class:* William Fraser Annand, University College; Elizabeth Bolton, London School of Medicine for Women; Alexander George Gibson, B.Sc., Oxford University; and Frederick William Weeks Smith, St. Thomas's Hospital. *Third Class:* Frank Alcock, Owens College; Frederic Wood Jones, London Hospital; and Alexander Moxon Webber, Guy's Hospital.

P [illegible] *—First Class:* George Hall (Exhibition and [illegible] ollege; Thomas de Smith (Gold Medal), [illegible] and London Hospital; and Alexander [illegible] Hospital. *Second Class:* Joseph Anthony Terrière, University College; Alexander George Gibson, Oxford University; Frederic Wood Jones, London Hospital; Gerald Warren Russell, Guy's Hospital; and Kenrick Stanton Wise, St. Bartholomew's Hospital. *Third Class:* Seymour Gilbert Barling, Birmingham University; Neville Samuel Finzi, University College, and Maurice George Louisson and Henry Francis Bell Walker, Guy's Hospital.

Organic Chemistry.—Second Class: Ernest Edgar Maples, St. Bartholomew's Hospital. *Third Class:* Kenrick Stanton Wise, St. Bartholomew's Hospital.

Materia Medica and Pharmaceutical Chemistry.—First Class: Ernest Edgar Maples, St. Bartholomew's Hospital, and Arthur Campbell Stark (Exhibition and Medal), Westminster Hospital. *Second Class:* Sophie Grace Hacking, B.Sc. London School of Medicine and Bedford College. *Third Class:* Joseph Anthony Terrière, Neville Samuel Finzi, and George Hall, University College; Philip Rees, B.Sc., Charing Cross Hospital; and Gerald Warren Russell, Guy's Hospital.

* Obtained number of marks qualifying for the Medal.

The foregoing list, published for the convenience of candidates, is provisional only, and is not final until the reports of the examiners shall have been confirmed by the Senate.

SOCIETY OF APOTHECARIES OF LONDON.—In July the following candidates passed in the subjects indicated:—

Surgery.—C. H. Allan (Sections I. and II.), London Hospital; A. G. H. Anthonisz (Section I.), University College Hospital; F. A. Beattie (Sections I. and II.), Guy's Hospital; P. C. Burgess (Sect [illegible]). Child (Section I.), Charing-cross [illegible] (Sections I. and II.), King's [illegible] Section II.), Royal Free Hospita [illegible] 's Hospital; H. C. Hocken (Section II.), Cambridge and Westminster Hospital; C. E. A. Huddart (Sections I. and II.), London Hospital; R. L. Jones (Sections I. and II.), Middlesex Hospital; F. P. Joscelyne (Section II.), Leeds; C. C. Morgan (Section I.), St. Bartholomew's Hospital; B. E. Sansom (Section II.), St. Thomas's Hospital; C. V. Smith, University College Hospital; P. P. Tobit (Section I.), King's College Hospital; F. I. Trimmer (Sections I. and II.), London Hospital; A. G. Wilson (Sections I. and II.), Manchester; and E. Yoxall (Section I.), Birmingham.

Medicine.—F. A. Beattie (Sections I. and II.), Guy's Hospital; J. E. Bolton (Section I.), Leeds; G. M. Crockett (Section I.), K. A. Dawson (Section I.), and E. A. Dunn (Section II.), Royal Free Hospital; H. C. Hocken (Sections I. and II.), Cambridge and Westminster Hospital; F. P. Joscelyne (Section II.), Leeds; A. E. Malaher, St. Thomas's Hospital; M. E. Martin (Section I.), Royal Free Hospital; E. S. Perkins, Leeds and Guy's Hospital; H. Richardson (Sections I. and II.), Leeds; P. G. Sheppard (Sections I. and II.), Cambridge and Liverpool; J. E. Skey (Section I.), Westminster Hospital; and A. G. Wilson (Sections I. and II.), Manchester.

Forensic Medicine.—F. A. Beattie, Guy's Hospital; J. E. Bolton, Leeds; G. M. Crockett and K. A. Dawson, Royal Free Hospital; E. H. Forjett, Edinburgh; C. J. Francis, Guy's Hospital; H. C. Hocken, Cambridge and Westminster Hospital; M. E. Martin, Royal Free Hospital; E. S. Perkins, Leeds and Guy's Hospital; F. P. Rose, London Hospital; J. E. Skey, Westminster Hospital; and A. G. Wilson, Manchester.

Midwifery.—F. A. Beattie, Guy's Hospital; F. G. Bennett, University College Hospital; F. J. Birks, Sheffield; P. J. R. Bucknill, Manchester and Dublin; W. V. Braddon, Cambridge and Manchester; A. N. Collier, Manchester; W. H. Crossley, St. Bartholomew's Hospital; W. R. Davies and C. W. Gibson, Guy's Hospital; J. M. King, University College Hospital; E. A. Le Maistre, London Hospital; D. E. Lockwood, Royal Free Hospital; M. B. Oliver, University College Hospital; J. A. W. Webster, St. Mary's Hospital; and A. G. Wilson, Manchester.

The diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery;—F. A. Beattie, F. J. Birks, P. J. R. Bucknill, E. A. Dunn, H. C. Hocken, F. P. Joscelyne, A. E. Malaher, C. V. Smith, and A. G. Wilson.

DEPUTY CORONER FOR NORTH SOMERSET.—Mr. R. Whiteside Statham, M.R.C.S. Eng., L.S.A., of Cheddar, has been appointed deputy coroner for North Somerset owing to the resignation of Dr. J. Wallace of Weston-super-Mare.

UNIVERSITY COLLEGE, CARDIFF.—The registrar of Cardiff University College has received an intimation from Dr. Isambard Owen stating that he is unable to accept the appointment of principal of the college.

A NEW MEDICAL JOURNAL.—An adjourned meeting of members of the medical profession practising obstetrics and gynæcology was held in London on July 24th under the presidency of Sir John Williams, at which it was unanimously resolved to establish a new journal to be called *The British and Colonial Journal of Obstetrics and Gynæcology*, and to raise the funds required for its publication by the formation of a limited liability company.

PRESENTATION TO A MEDICAL PRACTITIONER.—Dr. A. Davidson, for over five years senior assistant medical officer at the Dorset County Asylum, has, on the occasion of his leaving to take up work in the colonial service, received from the officers and staff a silver tea service, consisting of four pieces. The inscription on the teapot is:—"Presented to A. Davidson, M.D., by the officers and staff of the Dorset County Asylum in appreciation of his zealous work and kind attention."

NEWPORT (MON.) HOSPITAL.—The new hospital at Newport, which has been erected at a cost of over £30,000, is now completed, and the patients have been removed from the old building which was recently sold for £3900. The new structure stands on four and a half acres of land and will provide accommodation for 84 in-patients. The medical staff invited the local members of the profession to pay a visit of inspection on July 25th, and the formal opening by Lord Tredegar has been arranged for August 5th.

FREEMASONRY.—Medical Freemasons may be glad to hear of a new song entitled "The Freemason," written and composed by Dr. T. Wilson Parry and dedicated by permission to the Most Worshipful Grand Master of England, H.R.H. the Duke of Connaught, the proceeds of the sale of which will be given to the Royal Masonic Institution for Girls. Copies may be obtained from the author, Youlgreave, Bakewell, Derbyshire, or from Messrs. Kenning and Son, Great Queen-street, London, W.C., price 1s. 6d.

Parliamentary Intelligence.

HOUSE OF COMMONS.

THURSDAY, JULY 18TH.

The Army Medical Service.

Service; was he aware that in sever
proportion, of the men joining the
qualifications; and, seeing that five of the members of the committee represent London schools, could he explain why only one had been allotted to Ireland and one to Scotland; and would he give a return of the medical men in the Indian, British, and naval services, distinguishing those holding English, Irish, and Scotch qualifications for the years 1890, 1895, and 1900; and would anything be done to increase the representation of Ireland in the composition of the committee.—Mr. BALFOUR replied: The members of this committee were chosen not with a view of representing various nationalities but to render the Secretary of State practical assistance in the task of my right hon. he some time ce, and he has

The Nursing Question in Ireland.

Mr. WILLIAM JOHNSTON asked the Chief Secretary to the Lord Lieutenant of Ireland (1) whether he was aware that an inquiry had been held in Downpatrick by a medical inspector of the Local Government Board as to the necessity of providing a qualified midwife for Strangford Dispensary District, and that it was proved that there had been from time to time deaths from puerperal fever, from improper nursing, before a regularly qualified midwife was appointed; and (2) seeing that since the resignation of the last holder of the position, on May 1st, 1900, the guardians had persistently refused to appoint a successor, could he say whether there was any power in the Local Government Board to compel the Downpatrick guardians to make the appointment.—Mr. WYNDHAM replied: The facts are as stated in the first paragraph. The Board has frequently exhorted the guardians to appoint a midwife for this dispensary district since the occurrence of the present vacancy in May, 1900. The reply to the second paragraph is in the affirmative. The Board will again communicate with the guardians, insisting on the necessity for such an appointment.

Sanitary Defects in Post-offices.

Mr. SCHWANN asked the Secretary to the Treasury, (as representing the Postmaster-General, whether he was aware that the British Postal

Mr. YOUNG he could state how n Department, and in what proportion they were to the English and Scotch graduates.—Mr. BRODRICK replied that the number of Irish graduates was 334, being 37 per cent., as compared with English 35 per cent. and Scotch 28 per cent.

Medical Professorships in Ireland.

Mr. MACARTNEY asked the Chief Secretary to the Lord Lieutenant of Ireland if he could state why the appointments to certain medical professorships in the Queen's College, Belfast, had been limited to a term of seven years, whereas in the Queen's College, Cork, similar appointments had been recently made for life.—Mr. WYNDHAM replied: ars, dies ses the

The Condition of the Concentration Camps.

The Increasing Use of Cocaine.

Mr. MACDONA asked the Home Secretary whether his attention had been called to the death of two actresses caused by taking poisonous

Drunkards Bill.

This Bill, introduced in the House of Lords by the Bishop of Winchester and very much amended in that chamber at the instance of the Government, was withdrawn at this sitting from the House of Commons and consequently abandoned for the session.

TUESDAY, JULY 23RD.

The Dysentery Commission.

Sir WALTER FOSTER asked the Secretary of State for War whether

received from the Dysentery Commission.

Dental Provision at the Duke of York's School.

Mr. CATHCART WASON asked the Secretary of State for War whether his attention had been called to the fact that there was no dental

the boys have been sent to a dental surgeon or to the dental hospital. This would appear to be sufficient.

The London Water Question.

On the
formally
companie
Bill introduced by a private member can be passed or even substantially advanced during the present session.

THE NEW FACTORY AND WORKSHOP LEGISLATION.

PROCEEDINGS IN THE GRAND COMMITTEE.

At the meeting of the Grand Committee on Thursday, July 18th, very few points of interest to medical men were raised. In connexion *registers to be kept in every factory moved an amendment to have* among the workers inserted l so, he said, in order that married women might not be compelled or allowed to work in factories or workshops immediately before or after confinement. Mr. RITCHIE refused to accept the amendment, saying that no case had been made out for it and that it would be a

the law as it stood were literally carried out the medical officer of health would have to report every workshop in which he found a child or young person employed, even though it was regularly inspected. Clause 40—where there is no certifying surgeon for a factory or workshop the poor-law medical officer for the district in which the factory or workshop is situated shall act for the time being as the certifying surgeon for the factory or workshop—was passed by the committee without a word of comment. When a proposal was made to bring post-offices under the Factory

would be entirely upset but he assured the committee that he would do everything in his power to see that post offices were maintained in a sanitary condition.—Mr. STRACHEY suggested that his amendment might be altered so as to cover only inspection as to sanitation, but Mr. RITCHIE said that he could not accept it even in this modified form.—The committee rejected the amendment by 23 to 13 votes.—The question which occupied most time at this sitting was the question of the regulation of laundries. In the Bill as introduced it was proposed to place all laundries under the Factory Acts, but in the case of laundries in religious and charitable institutions to modify the ordinary factory inspection by entrusting it to a visitor to be agreed upon by the chief factory inspector and the managers of the particular institution. *The Irish members objected to any alteration in the existing state of the law and threatened opposition to the Bill as a whole* on the provision with regard to laundries in religious and charitable institutions. In these circumstances Mr. RITCHIE announced that rather than lose the Bill he would agree to the withdrawal of the provision and the insertion in the clause of words declaring that nothing in the clause should refer to institutions conducted in good faith for religious or charitable purposes. While he said this he intimated that he was still convinced that these institutions should be dealt with, and he would not commit himself or the Government in any way to non-dealing with the question on some other occasion. After a long and somewhat heated debate the Committee agreed to the demands of the Irish Members by 30 to 24 votes. No doubt the subject will be discussed again when the report stage of the Bill is reached in the House of Commons.

Another meeting of the committee was held on Tuesday, July 23rd.—On the motion of Mr. RITCHIE the following new clause was inserted in the Bill—viz.: (1) If the Secretary of State is satisfied that the provisions of the Factory Acts as amended by this Act, or of the law relating to public health in so far as it affects factories, workshops, and workplaces, have not been carried out by any district council, he may, by order, authorise an inspector to take, during such period as may be mentioned in the order, such steps as appear necessary or proper for enforcing those provisions; (2) an inspector authorised in pursuance of this section shall, for the purpose of his duties thereunder, have the same powers with respect to workshops and workplaces as he has with respect to factories; and he may for that purpose take the [illegible] the provisions of the Factory Acts or o[illegible] or for punishing or remedying any [illegible] the district council; and he shall be [illegible]ict council all such expenses in and about any proceedings as he may incur and as are not recovered from any other person; (3) Section 1 of the Act of 1891 is hereby repealed."—Sir CHARLES DILKE moved to insert a clause giving the Secretary of State power to make orders prescribing for any class of factories or workshops where children, young persons, or women are required in the course of their employment to lift heavy weights, the highest limits of weights that may be lifted by these children, young persons, or women. He explained that while legislation of this kind was novel in this country it was not unknown on the continent, and was found to work well there.—Mr. RITCHIE, while declining to accept the clause, said that whatever powers might exist in the hands of the certifying surgeon in the direction indicated would be exercised. In the case of children the certifying surgeon might make it a condition in granting a certificate of fitness that the child should not be employed in lifting heavy weights, or he might fix a limit of weight to be lifted.—After some discussion Sir CHARLES DILKE agreed to withdraw the clause.—A proposal made by Captain JESSEL to have the notices with regard to anthrax and lead and arsenical poisoning sent in the first instance to the medical officer of health for the district instead of the chief inspector of factories was not pressed, Mr. RITCHIE pointing out that it would interfere with the administration of the law and lead to delay. Sir FORTESCUE FLANNERY moved to insert in the Bill this clause—viz.: "Upon every notification by a medical man of a case which he believes to be anthrax poisoning the medical practitioner attending the patient shall, if no injury to the patient would, in the opinion of the medical practitioner, arise therefrom, immediately forward a specimen of the serum to a bacteriological expert approved by the Secretary of State for bacteriological examination, and in each fatal case of anthrax a specimen of the serum taken as soon after death as possible shall be forwarded in like manner by the practitioner who certifies the death." The hon. member having explained that anthrax was communicated with great facility to workers in wool, skin, and hair, said that during the last 10 or 15 years the disease had very much increased in this country. In 1899 there were 55 cases and in 1900 there were 37 cases. Unfortunately most of the cases were fatal. The disease was not very well understood by medical men. They themselves admitted that great necessity existed for further examination and research with regard to it. The Home Office had very properly given the greatest facilities in their power for research in the hope of checking the disease and there had been issued to certifying surgeons a memorandum of invitation and facilities had also been given for the bacteriological examination of specimens taken from infected persons. The clause he proposed had been approved by employers and employed in the West Riding of Yorkshire, but serious difficulties had been pointed out by the medical profession, and therefore he proposed to alter his clause so as simply to state that the Home Secretary might by order make regulations for the better bacteriological investigation of anthrax.—The CHAIRMAN of the committee said that if the hon. Member desired to make his proposal in this form he would have to do so at a later stage in the proceedings. The consideration of the subject was consequently postponed. The committee shortly afterwards adjourned.

DEATHS.

BLAMPIED.—On June 29th, at Sandy Brooke, St. Peter's, Jersey, John William Blampied, L.S.A., M.R.C.S. Eng., L.M. Dubl.

GORNALL.—On Thursday, July 18th, after a long and painful illness, John Hankinson Gornall, M.R.C.S., L.S.A., J.P., during 21 years Medical Officer of Health of the Borough of Warrington.

SHETTLE.—On July 21st, at Nailsworth, Gloucestershire, Richard Charles Shettle, M.D., aged 70, for 23 years Physician to the Royal Berkshire Hospital.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

MEDICAL REFEREES AND THEIR REPORTS: IMPORTANT DECISION OF THE HOME OFFICE.

AT the Southwark County Court on July 23rd, his Honour Judge Addison, K.C., said he desired to make public a matter which affected the practice of all county courts in regard to the Workmen's Compensation Act. A short time since Messrs. Barrow Bros. applied to terminate an award to an old man named Bowden under the Workmen's Compensation Act, alleging that he had quite recovered from the effects of the injury and was then suffering only from old age. The old man's medical attendant, however, gave it as his opinion that he was still suffering from the effects of the injury, and as there was this contradiction between the two medical men he (his Honour) referred the man and both reports to the medical referee appointed under the Act by the Home Office. Upon the medical referee's report he decided that the award should continue. After he had referred the case an application was made to him that the examination should be conducted in the presence of the solicitor to each party, but he refused it on the ground that the examination should be conducted privately and that if lawyers were allowed to attend the costs of the case would be piled up and the object of the Act would be defeated. Subsequently application was made by one of the parties for a copy of the medical referee's report, but he refused to grant it, merely stating that the substance of the report was in favour of the workman. It was then stated that a contrary practice prevailed at a county court for the proceedings and judge of which he had the greatest respect, but he refused to be guided by this because he thought that perhaps in the case quoted the judge in question had not considered the matter or had acted with the consent of each party. He, however, communicated with the Home Office in regard to the matter and he had now received a reply from that quarter stating that the authorities altogether approved of his decision that a medical referee was not to be attended by lawyers at all, but was to make his examination privately with the contradictory reports of the medical gentlemen in the case before him. As regarded the supplying of a copy of the report to the parties, the Home Office held that the report was primarily for the judge and he ought not to show it to anybody, but that he could use his discretion as to whether it would be right to show it to the parties should they ask to see it. He would use his discretion in the matter and would never reveal a report except under very exceptional circumstances, because he felt that a medical men who had to decide impartially between two other practitioners should not be exposed to the sort of controversy or contradiction that would result if those against whom he decided were allowed to criticise his report and to pull it to pieces. Further, he was of opinion that a medical referee would not report with the same fulness and confidence if his report was to be made a public document. Therefore he would follow the course which he had adopted and would refuse to allow any lawyers to attend the examination or to grant them copies of the referee's reports.

"ACME" PURE WOOL UNDERCLOTHING.

WE have received from Messrs. Charles Bayer and Co., of Victoria-buildings, Golden-lane, London, E.C., a specimen undergarment made of the above material. Both microscopical and chemical examination proved the fabric to be all pure wool, and macroscopical investigation showed the wool to be of a specially fine, soft, and elastic variety, of a net-like texture, permitting the free performance of the excretory function and at the same time protecting the body from cold. Owing to its extreme softness and lightness it is not oppressive or irritating to the skin. This material is particularly well adapted for clothing in cold, damp, and changeable climates.

THE TWO SIR MICHAEL FOSTERS.

SOME readers of the leading article on the Russell trial in the *Times* of Friday last, July 19th, may have confounded the Sir Michael Foster there referred to as an authority on State trials with the eminent member of our own profession of the same name. It may be well to explain that the authority referred to was Sir Michael Foster, a judge of the King's Bench, who lived in the latter part of the Stuart and early part of the Hanoverian periods, "a very great master of Crown law," according to Sir William Blackstone.

THE DUST NUISANCE.

PUBLIC attention is once more being directed to the intense nuisance caused by the conveyance of dust refuse through the streets in carts. The nuisance is only in part mitigated by the use of covered-in carts, for the dustman generally manages to shoot a load into the cart in such a way as to raise as big a cloud of dust as possible, and this is generally done at a time when the streets are most crowded. The bacteriology of dust is appalling and there is not the smallest doubt that dust is responsible not only for certain respiratory affections, inflamed eyes, but for other disturbances also such as, for example, headache. [illegible] probable, moreover, that wood pavements contribute their quota of dust in the streets owing to the ease with which wood disintegrates. It is clear, however, that some people enjoy a special immunity from the mischievous and offensive properties of dust, and a better example of this class of person could not be found than in the innocent dustman himself. He will be found [illegible] roadside between his jobs [illegible] his 'bread-and-butter' [illegible] and he can even be caught [illegible] his mouth, in spite of which dustmen appear to be by no means an unhealthy class. But the fact that he is "used to it," or immunised, so to speak, is no reason why others should be exposed to such possibilities as we have pointed out and that there be no complaining in our streets our authorities should give more attention to this matter. The nuisance is a very real one.

A POINT IN PUBLIC HEALTH.

To the Editors of THE LANCET.

SIRS,—I should be glad of a reply to the following. The occupants of the dwelling-house in connexion with railway-station refreshment-rooms are suffering from the effects of defective drainage. Has the sanitary authority of the urban council the same power to deal with this as they would with any other insanitary property?

I am, Sirs, yours faithfully,

July 23rd, 1901. VERITAS.

⁂ We know of no provision which in this case would bar a district council from adopting the ordinary procedure to abate nuisances, such as defective drains, in connexion with a dwelling. Our correspondent probably has in mind the exemptions from the operations of by-laws which have been allowed to railway companies in the case of buildings used for the purposes of the railway (Public Health Act, 1875, Sec. 157).—ED. L.

LOCUM-TENENTS.

To the Editors of THE LANCET.

SIRS,—Will you allow me through THE LANCET to give those requiring the services of a locum-tenent a profitable hint? I at one time never made arrangements with the agents except by wire, giving only very short notice when I required a man, &c. I have lately found that good and reliable men will not accept engagements at short notice—i.e., by wire. They like to know where they are going and to have some knowledge of the practice and principal. By giving an agent sufficient notice I have had first-rate men. Of course the ne'er-do-well who spends his money as soon as, or perhaps before, he earns it, does not care where he goes or how he does his work, but the better class of men like a few days' rest between each post. My last locum, an F.R.C.S. Eng., said he never took any notice of the agent's wires and preferred to enter into an arrangement by advertisement. Trusting this hint may be of use, I am, Sirs, yours faithfully,

July 22nd, 1901. M.D. BRUX.

A WARNING.

To the Editors of THE LANCET.

SIRS,—A large number of members of our profession have been r ceiving begging letters from a man signing himself "W. Dyer Frazer pleading want of means consequent on illness and loss of income owin to the situation in South Africa. The only W. Dyer Frazer in the pr fession is at the present moment in South Africa and is not in need o pecuniary assistance. The police have been communicated with and warrant has been issued. The writer has at present disappeared, but th police consider that he is probably writing more letters from a differen address and over a different signature. Would, therefore, anyone wh receives a begging letter, however signed, the *bona fides* of which is i question, kindly forward it to me or to Detective-Sergeant Harri Marylebone Police-station, W.

I am, Sirs, yours faithfully,

31, Welbeck-street, W., July 22nd, 1901. HERBERT C. CROUCH.

"EXPENSES AT CARLSBAD AND HOMBURG."

To the Editors of THE LANCET.

SIRS,—In reply to the inquiry in THE LANCET of July 13th, p. 116 the following facts may be useful. I lived at Homburg in 1894 from August 15th to Sept. 3rd, as a bachelor, and paid for lodging from 11*s*. 6*d*. to 12*s*. 6*d*. per week, which included a meagre breakfast, and I got a good dinner every day at a restaurant for 2*s*. 2*d*. per day. As a stranger I had also to pay a tax of 16*s*. I do not know whether this inhospitable law is still in force. The tax admits you to the use of the Kurhaus, with its reading-rooms, newspapers, and gardens, and good music two or three times a day, all gratis.

I am, Sirs, yours faithfully,

July 22nd, 1901. G.

⁂ A medical man is, we believe, exempt from the Kurtax.—ED. L.

THE HOT-AIR BATH.

To the Editors of THE LANCET.

SIRS,—There is much talk about cooling drinks, light clothing, &c., but the one real "cooler" is seldom mentioned. Every year I live I am more and more astounded at the attitude shown by the profession—teachers of healthy living—towards the hot-air, or so-called Turkish, bath. As far as I can judge not more than 10 per cent. of the profession are regular bathers; about 40 per cent. may have once had a bath, and 50 per cent. take a positively hostile attitude—fear "catching cold" after, or being "weakened" by the process—simple delusions.

I am not referring to the hot-air bath as a remedy but as a luxury in health or as a preserver of health. As an old bather I have for years debated in my own mind whether the thorough "cooler" one gets by the process in weather like the present, or the real lasting "warm through" in bitterly cold weather is the more enjoyable, and I cannot make up my mind. "But I can't spare the time," most people say. One hour in winter time and one and a quarter hours in summer is ample if you know how to bathe. Expense—well, at one of the most capacious and well-ventilated baths in London—Caledonian-road, close to King's Cross Metropolitan Station—10 tickets can be got for 10s., and "number one" shampooer is one of the best I have ever met with. As a "nerve tonic"—but there, the subject is an immense one, and it is [illegible] just now to [illegible]

M.D. Dub.

◆

W.—1. We cannot attempt to answer the first part of our correspondent's question. 2. Either the Berkefeld or the Pasteur Chamberland filters may be used.

Tabloid.—So far as we know there is nothing illegal in the custom, but it is unnecessary. The examinations for the triple qualification include one in midwifery.

Dr. W. E. F. Tinley.—1. The London Hospital has an installation for the purpose. 2. Our correspondent should write to Mr. Malcolm Morris.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (29th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St [illegible] (2.30 P.M.), Middlesex (1.30 P.M.), [illegible] (2 P.M.), Samaritan (Gynæcologic [illegible] oho-square (2 P.M.), Royal Orthopædic [illegible] Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (2 P.M.).

TUESDAY (30th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M. and 6 P.M.), Royal Ear (3 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden square (9 30 A.M.).

WEDNESDAY (31st).—S[illegible] (2 P.M.), Royal Free [illegible] (3 P.M.), St. Thoma[illegible] (9.30 A.M.).

THURSDAY [illegible]

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

BRITISH MEDICAL ASSOCIATION MEETING AT CHELTENHAM.

DURING the forthcoming meeting of the British Medical *Association at Cheltenham the representatives of* THE LANCET can be consulted at the Queen's Hotel with regard to our reports of papers and proceedings.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol. I. of 1901, which was completed with *the issue of June 29th, and the Title-page to the Volume,* were given in THE LANCET of July 6th

VOLUMES AND CASES

VOLUMES for the first half of the year 1901 are now ready. Bound in cloth, gilt lettered, price 18s., carriage extra.

Cases for binding the half-year's numbers are now ready. *Cloth, gilt lettered, price 2s., by post 2s. 3d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET *at their Offices, 423, Strand, W.C., are dealt with by them!* Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

During the week marked copies of the following newspapers have been received:—*Liverpool Daily Post, Leeds Mercury, Yorkshire Post, Hertfordshire Mercury and County Press, Mining Journal, Local Government Chronicle, Reading Mercury, Windsor and Eton Express, South African News, Surrey Advertiser, Local Government Journal, Bristol Mercury, Aberdeen Journal, Aberdeen Weekly Free Press, &c.*

Communications, Letters, &c., have been received from—

A.—Mr. J. Adams, Rye; Messrs. Allen and Hanburys, Lond.; Messrs. Arnold and Sons, Lond.; Messrs. Armour and Co., Lond.; Messrs. Andrew and Suter, Lond.; Dr. J. F. Armstrong, South Shields; Autochrome Co. Lond.; Mr. T. B. Adam, Lond.

B.—Mr. C. A. M. Bailey, Lond.; Messrs. Boot and Son, Lond.; Mr. W. H. Brooks, Leicester; Birmingham Gazette Co.; Bristol General Hospital, Secretary of; Messrs. C. Birchall, Liverpool; Birmingham Hospital for Skin Diseases, Secretary of; Messrs. W. H. Bailey and Son, Lond.; Lieutenant-Colonel David Bruce-Maitland, R.A.M.C., Cape Town; Mr. W. G. Burcombe, Lincoln; Dr. C. W. Buckley, Buxton; Mr. E. Brady, Haydock; Dr. Clark Bell, New York; Mr. Thos. Bayley, Lond.

C.—Dr. J. A. Cutter, New York; Mr. G. L. Cheatle, Lond.; Messrs. A. Clicquot and Co., Lond.; Dr. Carron de la Carrière, Paris; Cardiff Infirmary, Secretary of; Messrs. Condy and Mitchell, Lond.; Clayton Hospital, &c., Dispensary, Wakefield, Secretary of; Cumberland Infirmary, Carlisle, Secretary of; C. B. M. B.; Messrs. J. and A. Churchill, Lond.; Mr. Crofts, Lond.; Cape Colony, Medical Officer of Health of; Mr. Mayo Collier, Lond.; Dr. D. A. Coles, Haifa, Palestine; Messrs. Corner and Donald, Dumfries.

D.—Dr. G. W. Davis, Sidcup; Mr. A. B. Duprey, Grenada; Mr. E. Darke, Lond.; Dr. Morgan Dockrell, Lond.; Mr. G. M. Dawkes, Pontypridd; Messrs. S. Deacon and Co., Lond; Messrs. W. Dawson and Sons, Lond.; Mrs. Dale, Chiswick.

E.—Messrs. A. Elder and Son, Edinburgh, Electrical Standardising and Training Institute, Secretary of; Miss N. Evans, Bexley.

F.—Dr. R. W. Felkin, Lond.; Messrs. Feeney and Co., Birmingham; F. D. H.; Messrs. C. Fryer and Sons, Lond.; Dr. E. W. W. Farmer, Lond.

G.—Dr. R. Galloway, Aberdeen; Mr. T. H. Gough, Dudley; Messrs. H. Gilbertson and Son, Lond.; G.P.O., Secretary of, Great Eastern Railway Co., Continental Traffic Manager of; Mr. C. H. Garland, Lond.; Dr. J. G. Gornall, Warrington; Messrs. Gordon and Gotch, Lond.; General Infirmary, Leeds, General Manager of; Mr. J. Gay, Lond.

H.—Mr. Reginald Harrison, Lond., Mr. T. Bishop Harman, Lond; Messrs. Hewlett and Son, Lond.; Dr. S. M. Hamill, Burnham; Mr J. Herbert, Whitby; Hamilton Association, Lond., Secretary of; Dr. A. Hillier, Lond.; Horton Infirmary, Banbury, Secretary of; Howard Association, Lond.; Miss Homersham, Lond.; Mr. J. W. Harrison, Soothill; Mr. A. D. Hajj, Badari, Egypt; H. H. C. D.

I.—Dr. W. A. Illingworth, Leamington Spa; Dr. J. Ince (I.M.S. ret.), Swanley; Imperial Argus, Lond., Manager of; Messrs. Ingram and Royle, Lond.

J.—Mr. W. E. Joliffe, Rathgar, Dublin.

K.—Dr. A. Kinsey-Morgan, Bournemouth; Mr. B. Kuhn, Lond.; Lieutenant-Colonel Kirwan, Lond.; Messrs. R. A. Knight and Co., Lond.

L.—Mr. J. W. Livingstone, Stanhope; Herren Luppo and Heilbronner, Munchen; Lagos, Resident Medical Officer of; Mr. L. F. Leslie, Evesham; Messrs. Lee and Nightingale, Liverpool; Lee's Advertising Agency, Lond.; London Hospital, House Governor of; London Open-air Sanatorium, Hon. Secretary of; Dr. B. M. Lewis, Pontypridd; Liverpool School of Tropical Medicine, Secretary of: London Temperance Hospital, Secretary of.

M.—Mr. J. A. Maguire, Carmarthen; Mr. R. W. Marston, Lond.; Mendip Hills Sanatorium, Hill Grove, Secretary of; Dr. P. W. Macdonald. Dorchester; Mr. R. C. B. Maunsell, Dublin; M.R.C.S.; Dr. H. MacMurchy, Toronto; Mr. R. de Martini, Laughton.

N.—Mr. H. Norman, Catford; New York Life Insurance Co., Lond.; Northern Press Agency, Sunderland; Mr. H. Needles, Lond.

O.—Dr. G. W. Ord, Richmond; Dr. F. Orton, Lond.

P.—Mr. Y. J. Pentland, Edinburgh; Prideaux's Food Co., Motcombe; Preston Royal Infirmary, Secretary of; Parish of St. Mary Islington, Clerk of; Messrs. Parke, Davis and Co., Lond.; Dr. J. E. Prowse, Liverpool; Mr. F. E. Potter, Lond.; Messrs. Peacock and Hadley, Lond.; Major J. E. Pilcher, Carlisle, Pa.

R.—Mr. F. Rogers, Cheltenham; Messieurs Roger and Chernoviz, Paris.

S.—Dr. E. S. Sladen, Lond.; Messrs. G. Street and Co., Lond.; St. Mungo's College, Glasgow, Secretary of; Messrs. H. Sell, Lond.; Dr. S. H. Snell, Lond.; Dr. Howard Sinclair, Rostrevor, Ireland; Dr. J. L. Steven, Glasgow; Professor W. J. Simpson, Cape Town; Scholastic, Clerical, &c., Association, Lond.

T.—Dr. Bezly Thorne, Lond.; Tabloid; Dr. B. Tyrie, Keighley; Tottenham Hospital, Clerk of; T. H. M.

V.—Victoria Hospital, Folkestone, Secretary of; Veritas; Mr. J. W. Vickers, Lond.

W.—Mr. C. Williams, Woodhall; Worksop Dispensary, Hon. Secretary of; Mr. J. Williamson, Lincoln; Woodstock Rural District Council, Clerk of; West Bromwich Union, Clerk of; Messrs. Wallach Bros., Lond.; Miss E. Wright, Croydon; Messrs. J. Wright and Co., Bristol; Willings, Ltd., Lond.; W. T.; W. G.

Z.—Dr. Zabludowski, Berlin.

Letters, each with enclosure, are also acknowledged from—

A.—Mr. J. Allen, Norwich; Mr. H. Athill-Cruttwell, Bagshot; Association for Pure Vaccine Lymph, Lond.; A. W. H.; A. D.; Dr. A. Anderson, Wadsley; Dr. J. A. Aikman, Birnam; A. B. L.; A. E. L.; Apothecaries' Hall, Dublin, Secretary of.

B.—Mr. T. H. Brocklehurst, Stourbridge; Messrs. J. and H. Bell, Nottingham; Messrs. J. Beal and Son, Brighton; Messrs. Benson and Co., Lond.; Mr. W. R. Bhat, Pontypridd; Mr. G. P. Butcher, Plymouth; Mr. G. de V. Belson, Guildford; Mr. C. E. S. Brettingham, Ilchester; Mr. G. Barton, Charlcote; Messrs. J. H. Bower and Co.; Dr. B. W. Bond, Godalming; Mrs. B., Lond.

C.—Dr. Cotton, Newmains; Cairo Sanitary Department, Egypt; Mr. D. Crombleholme, Stanmore; Cortland Wagon Co., Lond.; Messrs. Cassell and Co., Lond.; Cheshire County Asylum, Macclesfield, Secretary of; Messrs. Edward Cook and Co., Lond.; Cantab (M.D. Brux.), Lond.; C. J.; Dr. G. Coates, Lond.; Dr. C. E. Cooper, Ivybridge; Mr. J. T. Croke, Hull; Mr. A. Connell, Sheffield; Dr. W. H. Corfield, Lond.; Mrs. Curtis, Yeovil.

D.—Dr. J. W. Davies, Port Talbot; Mr. R. Davis, Lond.; D. M. J.; Messrs. Dowie and Marshall, Lond., Mr. J. T. Davenport, Lond.

E.—Mr. John Evans, Bilston; Messrs. Eason and Son, Dublin; E. R.; E. F. H.; E. E.; Mr. T. F. Elmes, Sundays Well.

F.—Mr. B. Flood, Ballymahon: Messrs. Forsaith and Sons, Lond.; Fisherton Asylum, Salisbury; Dr. L. C. E. Forster, Bristol; Ferrum, Lond.; Messrs. J. S. Fry and Sons, Bristol.

G.—Mr. W. Greene, Amesbury; General Medical Council, Registrar of; Mrs. Gibant, Jersey; Grove House Private Asylum, Church Stretton; G. N. P.

H.—Dr. J. Holmes, Whitefield; Mr. J. Heywood, Manchester; Messrs. Hastings Bros., Lond.; Hereford County and City Asylum, Secretary of; H., Lond.; Messrs. Hogg and Son, Lond.

I.—Messrs. Ind, Coope, and Co., Chatham; Ipsi, Brighton.

J.—Jeyes' Sanitary Co., Lond.; J. P. S.; J. H.; J. K. W.; J.; J. R. L.; J. A.; Messrs. Jewsbury and Brown, Manager of; Mr. Y. M. Jones-Humphreys, Cemmaes; J. C. U.; Mr. G. D. Johnston, Vancouver.

K.—Mr. C. E. Keatley, Lond.; Mr. A. W. Kirwan, Oranmore; Dr. H. Kerr, Stone, Bucks; Messrs. Knight and Co., Lond.

L.—Dr. A. Leitch, Cornsay Colliery; Mrs. C. Lappin, Gilford, co. Down; Dr. L., Macclesfield; Locum, Portobello; Miss E. F. Lamport, Lond.; Liverpool Royal Royal Infirmary, Secretary of.

M.—Mr. W. J. Mynors, Colchester; Manchester Royal Infirmary, Secretary of; Middlesborough Corporation, Treasurer of; Manchester Medical Agency, Secretary of; Mr. J. Milne, Lond.; Mr. E. P. Marett, St. Laurence, Jersey; M.B., Blackburn; M.; Mr. J. Moynihan, Whitby; M. S.; M. S. M.; Mr. L. C. Martin, Woolston; Dr. H. Macnaughton-Jones, Lond.

O.—Osburne, Bexhill-on-Sea; Mr. A. Oberfoell, Lond.

P.—Mr. J. Pond, Norwich; P. A. L. F.; Messrs. Pownceby and Co., Lond.

R.—Mr. R. Roberts, Llanddeusant; R. S.; Mr. S. H. Rentsch, Week St. Mary; Mr. R. Rogers, Bow; Rector, Bexhill; R. J.; Rajahmundry, India, District Surgeon of; R. B. W.; Royal Halifax Infirmary, Treasurer of; Dr. R. L. Roberts, Ruabon.

S.—Mr. H. M. Speechly, Parkgate; Mrs. Skinner, Winchelsea; St. Bartholomew's Hospital, Rochester, Clerk of; Dr. C. S. Storrs, Reading; Messrs. M. Samuel and Co., Lond.; Mr. L. H. de V. Shaw, Beacon Ash; S. W. W.; Mr. R. H. Somerville, Edinburgh; Symons, Penzance; Salford Union, Clerk of; Springfield House Asylum, Bedford; Southampton County Borough Accountant of; Mr. P. J. Spencer, Lond.; Mrs. Shettle, Nailsworth; Miss E. Symons, Wadebridge; Sister Lucy, Branksome.

T.—Dr. M. Thomas, Llanfair; Dr. W. E. Tresidder, Nottingham; T. A. L.

U.—Union Assurance Society, Lond., Secretary of.

W.—Walker Hospital, Walker-on-Tyne, Secretary of; Dr. J. H. Waterhouse, Rotherham; Whitehaven Infirmary, Secretary of; Messrs. H. Wilson and Son, Lond.; W. C.

Terms for Position Pages and Serial Insertions on application.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 8, Rue Traversière, Asnières, Paris.

Address in Medicine:

FRIENDS IN COUNCIL.

Delivered at the Annual Meeting of the British Medical Association held at Cheltenham on July 31st, 1901,

BY JAMES F. GOODHART, M.D., LL.D. ABERD., F.R.C.P. LOND.,
CONSULTING PHYSICIAN TO GUY'S HOSPITAL.

DR. GOODHART, after the usual complimentary introduction, gave the keynote of his address as follows:

"The position of medicine, then, to-day, as I see it, is this: the living body, the clay between the potter (the doctor's), on the one hand, and the wheel (the blind guidance of animal life), on the other."

He then discoursed upon vitality, the living energy of the body. "Take these two points, the intricacy of the mechanism of the animal body and the indomitable animal spirit of life which innervates it. How do these react upon the practice of medicine and do we acknowledge the reaction as it exists?" From these two points Dr. Goodhart proceeded to discuss "the difficulties of medicine."

PATIENTS.

We must for a moment consider each of the two parties, their influence upon each other and thus upon the progress or otherwise of scientific medicine. Are we gradually surging on by a natural process of evolution to a perfect system of the treatment of disease? Is the management of the sick man and the ailing man in the present day as perfect as it might be? On the larger side of the subject—that of preventive medicine and the scientific knowledge of disease—it is obvious that great discoveries have been made in the recent past, and the dawn is surely breaking of a still more brilliant day. So far as this side is concerned I think it may be said that we are steadily working upwards to that time when much of the present gross disease—tuberculosis, microbic fevers, &c.—shall be no longer; though even here, if there were time, I might pause to show how a weak sentimentalism sometimes steps in to delay the promise of the future; but in the aspect with which we as physicians are concerned, the daily treatment of disease, with all the manifold details of the aches and pains that flesh is said to be heir to, one cannot but feel that there is room for improvement, both on the side of the patient as on that of the practitioner. Now on looking [illegible]d of disease, although [illegible] life is longer than it [illegible] often in request nor t[illegible]. I am here to cont[illegible]wing more and more sensitive about our health, more impatient when the flies of ill-health worry us, that we are crying more loudly for a cure for every disease, whether it be one that is commencing and curable or so advanced that—as, say, in a bad case of phthisis—the greater part of an organ is practically destroyed, and a restoration of its health impossible.

This is shown in several ways. In the first place the sick man wants to know too much. He wants to know what is the matter with him when it is not possible to tell him; moreover, he will have an answer, and if not he thinks the doctor an ignoramus, and calls in someone else. How blind he is not to see—it seems so obvious—that in this complex body of ours there must be hundreds of little accommodations between the various organs and parts that it is impossible to explain or be sure about, that there must be numberless [illegible] le[illegible] le[illegible] that look grave, and yet if we could only peer a little into the future, get just one glimpse behind the veil, we should see were just on the turn towards health, and no matter what drug was given would do well—the cradle these of many an ignorant man's reputation; and numberless cases that seem to be doing well that are just on the verge of a catastrophe, and these the grave of many a competent man's success. Oh if men would only think a little more, it seems so obvious that they must then see that even the best of us are but gropers in the dark, and that ignorance acknowledged is no proof of want of skill, rather is it a proof of thought and of the highest devotion to the advancement of our calling. Any fool can give a name to a disease if, as is too often the case, the letter satisfieth. But what if the name is wrong, and the name determines an important line of treatment, what if the letter killeth?

It is because the public will have a disease ticketed when there are no means of identification that these difficulties arise, and because it still sets such store by the man who plunges. How much better would it be if the obvious were better recognised, that the practitioner is but mortal, and if others than ourselves could take part intelligently in our doubts and difficulties. And having got a name for his complaint, from either wisdom or ignorance, the patient thinks his physic tumbles out of the same slot, and that between the two he will be cured offhand. Someone comes into your room and says "I have got to do this or that on a particular date and you must get me well by that time." It is the medical man or his medicine that has got to do it; there is no thought behind, as there should be, of "Will my tissues or the disease allow of this being done?" There is no idea of doubt, none of the necessity of waiting to see which way the cat jumps, none that the powers of medicine are limited in all sorts of ways and that there are numbers and numbers of instances where there is no indication whatever that medicine will do any good whatever: that waiting *for developments or subsidencies is the only skilful course.* Waiting is described as "nothing is being done for me," and someone else is called in with a "Can't you do something?" "Doctor, I'm just stuck," said a poor fellow to me the other day when all hope had left us, though keeping him radiant still.

And it is because life understands so little the common sense of this waiting, this doing nothing, this length of illness, and so on, that it understands so little the true value of consultations. The sick man or his friend has a rooted idea that when a second opinion is sought it is to set the first opinion right. Now the wise man is he who makes fewest—there is no man who never makes any—mistakes, and least of all in medicine. Our uncertainties are so thickly strewed on all sides that it is seldom that one is in a position to give a very positive opinion; but I think I may say, with an approach to certainty, that I am in accord with those who are in a similar position to myself, that the education of every member of the medical profession at the present day is so high, that it is seldom indeed that a consultation does not produce a well-thought-out and probable diagnosis from the practitioner in charge. It is not a case of right or wrong; it is not altogether a question of less or more experience: it is a meeting to discuss doubtful and difficult points to which each party contributes an equal share. But so little is this the light in which consultations are regarded that it has become a saying that "doctors in consultation always agree; doctors apart will always differ." I am constantly being annoyed, in all innocence, by being told that "I want a perfectly independent opinion," as if that were the last thing the applicant considered himself likely to get. An independent opinion too often means an opinion more in accord with the wishes of the patient than is the one which has been originally given. Medical men would be only too glad to discuss the doubtful points of a case with the patient or his friends, if those could be found who could appreciate them intelligently; but it is hardly to be expected that differences of opinion should be made much of when the sick man is unable to appraise them at their true value and puts trivial and important matters equally into the same scales of right and wrong, and when wrong always implies with them discredit. And discredit may come from the most worthless sources. For instance, one man may have ordered hot water for drinking, and No 2 says, "Drink cold water." It does not matter a mote in the sunbeam which of the two is drunk, but the symptoms change within a measurable distance of the alteration, and the undiscerning man puts it all down to "the new treatment." A change in the medicine is made, say more to ease the patient's mind than with any real expectation of influencing the course of the disease; and while one man reaps the credit the other has the blame, and each alike may be entirely innocent of the result. Then this morbid sensitiveness of people in the present day is well shown by the rapidity with which they fly to medicine. This fact is, I think, patent enough—it is to the practitioner, at any rate—for the number of new drugs for all sorts of maladies, imaginary and real, that are being daily launched upon us is bewildering in the extreme. A woman with migraine has gone the round of all the coal-tar products that were ever invented, as well as caffeine and other things, before she thinks of applying to our calling. Most people know all about lithia and piperazine and the respective merits of the various preparations of Carlsbad salts; they all have their own form of blue pill, which generally from the look of the prescription seems to date from before the flood. They have their own special dinner pill and an aperient pill as well; they know all about podophyllin, and euonymin, and cascara. They take their bismuth and soda for indigestion, mindererus spirit and Dover's powder for colds, camphor for cholera, chlorodyne for the stomach-ache; and one old gentleman that I have known, though he had been bred amongst medical men and was old enough to know better, was so enamoured of drugs that he took a daily dose of gentian and ammonia as his lunch.

Then, too, with what impatience do men and women in the present day rush into the not always sufficiently repellent arms of surgery. A little pain unnerves them and all they know of surgery is its successful side. It is a day of great things, and why should they not have the benefit of these advances? And so with an ache here or a pain there they undergo an operation. The energy of life that I have so often spoken of knows nothing of risks, knows nothing of shock, will hear nothing of waiting and rest in bed, and the disappointment in consequence is often considerable, although the operation was a great success.

DOCTORS.

And now for the potter who has more or less to fashion this clay as it somewhat impulsively rolls along under the momentum of the wheel of life. The simile is not a good one, for the practitioner is never a fashioner, although sometimes in the plenitude of his pride he conceives himself to be and then o'erleaps himself, not he, but his patient, unfortunately, falling on the other side.

What are we doing in this impatient, restless age to stem the tide, to stay the panic, to bid the people keep its head? I do not mean in the immediate present—for we always do our best for the patient according to our lights—but with our eye on the future and that continuous progress as individuals for which the Goddess of Medicine is marking time, and surely points us to. I do not doubt, I say, that everyone of us does his best for the man who consults him, but I am not sure that in attending to the exigencies of the immediate present we do sufficiently take heed of the future. And our failings in this respect are closely bound up with those of our patients, for we in our place are so anxious to overlook nothing and to cure disease, so enthusiastic in our belief in our power to accomplish what we wish. First may be put a morbid readiness on our part to detect disease. Engaged as we are in this pursuit there comes a risk that we too little appreciate the wide range of health—that is, how good a state of health is compatible with numberless slight and even sometimes considerable departures from normal. We tend to make our standard too severe for practical purposes. I will take an illustration from the heart. Here is an organ in which there are numberless slight departures from a rigid normal, both as regards its muscular action and functions, which mean nothing as regards the longevity of the patient, but to which a morbidly tender medical conscience refuses the title of health. Over and over again in the present day a heart is said to be strained, or weak, or dilated, or even diseased as to its valves from a want of sound appreciation of what is to be considered health, not for the general, but for the particular. One would almost think from all the talk one hears about dilatation of the heart, strains in healthy young people from trivial causes, the grave conclusions that are based upon, perhaps, some slight displacement of the impulse, &c., that the heart is so fragile an organ that it needs to be coddled from the cradle to the grave. It is the fountain of life certainly and therefore a very indispensable organ, but Nature gives to our comely as to our uncomely parts a strength sufficient for their day, and there is a large margin for emergencies in every part. It is for this reason that I hate the term "weak heart." It coffins, or, worse, throws useless upon society, many an otherwise useful life. Hearts are either diseased or healthy and, within its margin, it is a robust organ that is all the better for plenty of work. I tell you what it does not like and that is luxurious ease and one may well have a shrewd suspicion that many a one who coddles a weak heart dies of real disease which an indolent habit has produced.

Let me take another organ popular at the present day both with the medical man and his patient, and upon which both parties have, I fear, gone a trifle adrift. It shall be the stomach. Catarrh of the stomach is a term that is in most people's mouths, and it is a word that appears to have a strange satisfaction in the utterance. Catarrh is quite a sufficient disease, wherever it may be, to silence the anxious inquirer and no more questions are asked. But, as I have said before, the stomach does not catarrh—at any rate readily. It is a good, strong, healthy servant, with possibly a prejudice or two, and if you treat it fairly is really, quite unlike most servants of the present day, most obliging and thorough. And even if upon occasion you do not treat it with quite that sensitive regard that it is entitled to expect, you may hurt its feelings, as any want of consideration is likely to do to a faithful handmaid who has done her best; yet it is only a momentary estrangement, a little domestic concern that wants no third party such as rhubarb, or creasote, or salol may be, to rub the injustice in. A little carbonic acid to soothe its ruffled feelings and a kindly sorrow and repentance on the part of the master, with a penitential fast, and things will soon come right.

And while on stomachs I hear a good deal of a so-called dilatation of the stomach. Now a true dilatation of this organ is a comparatively rare thing, and when it occurs it often needs, and is benefited by, rather heroic measures. But the great part of these so-called dilatations are due to a passive relaxation of our inward parts, and this is due to the bankrupt condition of our abdominal brains. These and quite a number of other abdominal displacements are so common without any symptoms of any kind, that it is certain the condition is only a disease under special circumstances, and those special circumstances have more to do with the individual than with his displacement, and their best treatment is to let them severely alone. But the public won't have it. Who does not know the difficulty there is in preventing people from undergoing a serious operation for the purpose of stitching these harmless mobilities—for it is only quite exceptional that it is otherwise—into their places. It is the same in many another region—throats and noses suffer terribly from this lust of operation that has beset the public. Ears are now being swept into the panic, and I incline to think that the only region of our art that preserves its proper decorum is that of ophthalmic surgery, and it, I believe, reaps the reward of well-doing that is usual in this topsy-turvy world in being regarded by the *élite* as somewhat old-fashioned, and so it is supposed to be the thing to go abroad to skim the cream of skill.

But let me quit the domain of medical surgery to take up the question of our administration of drugs. It is told, as many of you know, of the late Sir William Gull that upon a medical man excusing himself for not having discovered the existence of a particular disease he remarked that it was as well that he had not done so, for that if he had he might have treated it.

DRUGS.

Now, why do we give drugs? To cure disease, you answer at once, and think the question unnecessary. But wait a minute; we give drugs for several other reasons, some of which are far less free from criticism. For example, drugs are often given, not because the disease demands one, but because the patient is not happy till he gets it: too often he is not happy even then. They are given sometimes to hide our ignorance, I fear, or to mark time while we watch and wait; they are given sometimes as a gambler on the Stock Exchange speculates in "futures," an enhanced reputation being the windfall that it is hoped to secure; and then we often give drugs as an experiment in the hope that they may do good. I will deal with this last more especially, for it is a reason for giving drugs about which the public are peculiarly sensitive and ill-informed. It is often said as a matter of prejudice against the hospitals of our country—than which none could possibly be conducted more humanely and considerately—that the patients are made the subjects of experiment. So they are. But this happens not only in the hospital. If it be true—and it is true—that you and I are unique in our way, and that it is this individualism of man that constitutes the great barrier of the evolution of any system of medication, it follows that each new patient who demands treatment is more or less a case for experiment, and it is by experiment of this qualified kind—upon the king as he sits upon his throne, as for the poorest being within his realm—not only that the value of drugs is established and new powers gained over disease, but by which an increase of knowledge of disease itself is gained. The cure of disease is always the fundamental object; but not far behind it should come the alert eye to watch the deviations from the hypothetic normal which the individual resistance or the drug in its action may show in the course of the case.

All treatment by drugs is more or less of an experiment, and it is, indeed, in this fact that the enormous number of new drugs daily poured upon us finds its justification. Many and many an ailment that afflicts mankind badly needs a remedy, but for which, as yet, no remedy is opportune; and who knows but what in each new drug some human ill may find alleviation? A druggist's shop is indeed a source of wonder and dismay to me, and I could indeed wish we were less the prey of the manufacturing chemist, but I would not for a moment even seem to discountenance new remedies. What I would discountenance is the giving of drugs by rule of thumb. Diseases run in fashions; I have mentioned one or two that seem to me in fashion now, and there are fashionable drugs which, while the sun shines upon them, become the darlings of society. Their popularity is enormous—far in excess of their merits; and by-and-by they sink into the cold shade of neglect. Who does not even now remember the boom of the antipyretics? A few of them have remained to us for other purposes; but as antipyretics who gives them now? They are not by any means valueless when given appropriately, but they were rushed for more than they were worth, and they are now buried by later booms, such as animal extracts and antitoxins, and many of these will be buried too. And then as to routine in the treatment of disease. I suppose there is not a single case of gout in the whole world that has not had sodium salicylate and other easily enumerated drugs, and had them freely; and why?—because they are supposed to eliminate the cause of the disease. I find that the British public know far more about uric acid and how to deal with it than I do with all my pains, and what men think they know in this respect, I fear that we, in the first place, and vulgar advertisement in the second place, have taught them. Yet I cannot understand how any reflective mind, making a careful study of gout in its clinical aspect, can settle down and bury itself in the doctrine that gout is a mere question of intake and output, and, if not, think of the harm that is done by false doctrine of this kind upon the thousands who are engaged in the hopeless struggle of dispossessing themselves of their fetish.

The open-air treatment of consumption, of which we are hearing much at the present day, is also bidding fair to come under the baneful influence of routine. "The new treatment," though it is hardly a compliment to our environment to call it so. What, think you, does the sufferer from consumption, and his friend, see in this? He sees a residence for a few months in a home, and a cure at the end of it. Is that what he has any chance of obtaining? Certainly not, and in proportion to the exaggerated hope will come the bitterness of the disappointment to the sick and the discredit to us. The benefit to be obtained in these sanatoria is that there will be learned a habit of life—what we mean by plenty of good food and plenty of fresh air; and having learned his lesson the tuberculous man will need to practise it all the rest of his life. There is no cure in this treatment as the sick man understands cure; for although it is true that there is no disease that is more often arrested than phthisis, it is equally true that there is no disease that has a more inveterate tendency to relapse, and I very much fear that when you come to strike the balance between arrest and relapse the latter has the best of it. Therefore if the open-air treatment is to take its real place and be of any abiding value the principles of the sanatorium must be introduced into the home.

And that reminds me of another fashionable idea that is now in vogue, and I will call it medical antisepsis. Antiseptics in lung disease have had a long day, tempered only by a momentary fall into heresy when it was proposed by those who ought to have known better that we should be converted into gasometers for the storage of sulphuretted hydrogen—and this was to cure consumption. I only mention this to show how much we need to keep our imaginations in check in thinking over the cure of disease. However, antiseptics in the lung from all the many inhalations up to iodoform, and finally creosote internally, have had a good innings and have not been without their minor successes, but it was very meet and right that the comparative inefficacy of such nauseous medicaments should drive us back into the arms of the great original antiseptic—fresh air. And perhaps for that reason we have now turned a somewhat cold shoulder to the lung and are directing our efforts to rendering the intestinal canal antiseptic and I hear daily of creasote and salol and all sorts of other well-meaning drugs being sent on this errand of reform. Far be it from me to decry the value of useful remedies, but I cannot help asking myself the question whether the staunch believers in intestinal antisepsis possess sufficiently cultured and liberal-minded noses to be good advisers to our intestinal apparatus. It is quite evident that stercorin, however much so to us, is not a *persona ingrata* to our colic mucous membrane; it is, indeed, bone of its bone; and it is possible that we might be none the healthier men and women even if our medical men got their wishes in this respect.

One other drug only will I wish to mention to illustrate my point, and that shall be the use of the bromides in epilepsy. Now, that these are useful drugs in this complaint no one will question to-day. But long ago it has gone forth from those who are in authority in such matters that after a person has suffered from epileptic fits the drug must be given regularly in considerable doses, and for long periods of time—a year or two, or more—to prevent their recurrence; and this advice is very generally acted upon. There is no doubt that it has become the routine treatment of epilepsy and as such I think it often does a great deal of harm; and I am by no means certain that it does any equivalent good.

THE DANGERS OF ROUTINE AND FASHION.

Now all this routine and fashion—and remember I have only taken one or two instances out of numbers that lie at my hand—I object to, and I do so because it all tends to establish false relationships between the medical man and his patient, and let me attempt to show you how. The patient first of all asks us for a name to his disease and whether we know or not we give him one. In so doing we, as I say, speculate in "futures," and that is a form of business that very often ends in bankruptcy. No remark is more frequent at a consultation than that we must give a name to the disease. I object to giving a name to anything I am not sure about and when a man says to me, "That is all very well for you, but it would never do for me," I object still more because the general practitioner is the great instructor of the public in matters medical. I have not a tithe of the influence that he has, and by giving names to symptoms that are doubtful in their significance, he is first of all losing an opportunity of insisting upon the dignity of ignorance; then he is conveying to the public the erroneous notion that we have the power of insight into problems that are at the time inscrutable; and we ultimately end in deceiving ourselves into thinking that we know much more than we do—an idea that is fatal to the progress of knowledge. There are hundreds of examples that might be given, but the various febrile disorders are the most fertile in discords of this sort. It is often absolutely impossible in the early days of typhoid fever to say what is the matter; equally is it absolutely impossible in many of the eruptive fevers to say what of several things will eventually declare itself. It is not ignorance but knowledge that halts. When I first entered Guy's Hospital some 36 years ago it was a common saying about one of our staff at that time—and certainly one of the best physicians of that day—that he knew so much that he could but seldom be prevailed upon to give a positive diagnosis. And it is true, as Sir Arthur Helps says in the book from which I have borrowed the title of this address, that knowledge brings doubts and exceptions and limitations that are all hindrances to vigorous statement.

Then a word about the evil of letting the public force our hand in the matter of drug-taking. I have already alluded to routine as destructive of all scientific observation, enabling as it does the giver to see only cures and nothing of failures, though they be in very truth staring him in the face. But I am now alluding especially to the numberless occasions when drugs are given, there being at the time no distinct indication for giving anything. There is no doubt that this is a very common and bad fault with us. I do not say that it must never be practised. There are times when the sick are not reasonable beings, and unless they have a bottle of medicine to anchor their faith to (oh, shifting sands!) they are in a state of unrest that is positively harmful to their progress. But there are multitudes who are not in this parlous state who are capable of listening to reason, but who as now, having been taught to look for their prescription or their bottle of medicine, have no idea of the value of advice only or of the need of the watchful eye. Why, we are all familiar with the "Are not you going to give me a prescription?" when you have been pouring in advice with much prodigality of tongue and had flattered yourself that you had gained a disciple; and there is no need to go far to be absolutely sure that the great body of the public, rich and poor, pay for our prescription, and that they do not value by a button any advice that lies outside it.

But I think that there is another reason for this indifference to the value of advice which, although it is perhaps one that savours of the sordid, I must nevertheless touch upon. I have often inwardly contrasted the two professions of law and medicine, how in the one advice pure and simple is sought and found and the givers thereof acquire positions of milk and honey and find themselves mounting to the high places of the land. In the other medicine passes for the consideration, and, well! the sellers thereof do not seem to possess themselves of many coveted places of honour. And if you ask me why this is I believe it to be because we make ourselves too cheap. Advice—just think of it! A product of so unique a value that when a man of great experience in the world of medicine dies his knowledge dies with him; no other man can supply his place and there is a dead loss to the community of a mine of unrealised information. You all know that very clever signboard in which a bullock is seen gazing yearningly upon a small jar of meat extract and exclaiming, "Alas! my poor brother." But I often wish that I could pot my brothers as they flit from off the stage; my trouble is that my masters die unbottled. And yet we "give" advice, and there are those in number who not only accept but ask the gift. Oh, dreadful degradation—that advice, a priceless article, should fall in value below cheese and butter.

It is told of the late Sir Andrew Clark, with what truth I do not know, that when he was asked to give gratuitous advice he said, "No; but I will give you the money with which you can purchase it." Whoever said this was a wise man, for on the one hand there was in the answer the generosity that knows no bounds of medicine to poverty; there was on the other the dignity and self-respect that fully understood the preciousness of the knowledge that he had the power to impart. We shall never make the public understand the true position of medicine until we set a higher value upon *ourselves* and upon the *advice* we give.

What better illustration could there be of the inutility of thus giving ourselves away than that so shrewd and penetrating and fair-minded a man as Mr. Joseph Chamberlain, in so grave a matter of right and wrong as the question of cheap consultation, should have declared that the question was settled by medicine upon the strictest trade union principles; and that another man, equally hard-headed if erratic, should agree upon that point, and then proceed to define trade unionism as "doing the worst possible work at the highest possible price." Cheap consultations! Philanthropy has, indeed, there got hold of the wrong end of the stick. Why, it is notorious that such is the generosity of medicine that there is not a needy person in the whole kingdom who cannot, if he need it, obtain the best opinion in the country gratuitously. The clergy, the army, the navy, artists, actors, actresses, clerks, artisans, and others pour into a practitioner's room or the hospital asking alms in the shape of advice and never get a refusal. And after it all we are insulted by being called trade unionists—"men who do the worst possible work at the highest possible price." And I honestly believe we have ourselves to thank for this in great measure, for we belittle the value of our advice in allowing the public to exalt so greatly the supremacy of physic.

That "the labourer is worthy of his hire" is but one side of the question, and not the best side, for it might be held to cover many a sordid act: the other and much the more important is surely this, "See to it that the hire is worthy of the labourer." And although expressed in these terms the face value may seem to be one of low ideals, I am far from thinking, as I speak, of any money consideration, but of the higher and nobler recompense of dignity and self-respect. And it is, in part, because I think that to careful observation it must seem that the very nobleness and generosity of medicine does tend somewhat to make us forget the importance to its well-being of these just rewards that I have chosen this subject for my address to-night.

On, then, my comrades, in your noble work till other voices, other years, shall bid you pause in other ways, according to their seeming. Mark well the hindrances to our onward progress that together we have traced to-night, be more than ever heretofore the steersman at the helm, to guide the sometimes teasy ship between the troubling eddies of the passing thought, and then your greater selves, firm anchored in "the spirit of the years to come," need reck not

"Lest the cause ye love
Should languish when your tender toil-worn hands
Are crossed in peace beneath the daisied sod!
The Means wax old and perishable prove,
The End endures eternally, and stands
Above the ages, face to face with God."

Address in Surgery:

SOME SURGICAL LESSONS FROM THE CAMPAIGN IN SOUTH AFRICA.

Delivered at the Annual Meeting of the British Medical Association at Cheltenham on August 1st, 1901,

BY SIR WILLIAM THOMSON, C.B., M.D.R.U.I., F.R.C.S.IREL.,

HONORARY SURGEON TO HIS MAJESTY THE KING IN IRELAND; SURGEON TO HIS EXCELLENCY THE LORD LIEUTENANT, K.G., AND TO THE RICHMOND HOSPITAL, DUBLIN.

SIR WILLIAM THOMSON commenced by making a feeling reference to the late Sir William Stokes who laid down his life in South Africa. He then passed to consider the entirely novel conditions under which the war in South Africa was fought. He gave some figures illustrative of the effects of rifle fire. In the American Civil War the killed were 17·97 per cent. of those hit. In the Spanish-American war, when the Mauser rifle was in use by Spain, the American killed were 11·9 per cent. of those hit. The latest figures from South Africa show that 14·8 per cent. of our men who were hit died. Small-bore bullets, continued Sir William Thomson, made ghastly wounds if they ricocheted and he quoted an unmistakeable instance of this that had come under his own eyes:

A soldier accidentally discharged his rifle at a distance of 10 paces. The bullet ricocheted and struck the victim on the inside of the thigh posteriorly to the femoral vessels. The entrance was more than an inch in diameter, the exit at the outer side was a wound two and a half inches in diameter, with great loss of substance. Here there was no doubt as to the weapon or the ammunition employed. The soft structures alone were injured, but they presented the appearance that one would expect as the result of some powerful local explosive.

WOUNDS OF THE SOFT PARTS.

The campaign in South Africa has presented many surprises. Perhaps none is greater than the large proportion of wounded who have recovered. Even severe wounds have responded to treatment in a manner which has surprised everyone having experience of surgical injuries. These happy results were due in the first place to the character of the bullet. The wound was in ordinary cases exceedingly small at both apertures, and the tendency was to close immediately. There was usually little hæmorrhage and the openings were quickly sealed by exudation. This was an important first step. The pointed end of the bullet made the area of primary collision with the surface struck quite minute, and being covered in a hard mantle it acted like a steel wedge driven with great velocity through the soft parts, rather cleaving than tearing its passage onwards. It appeared to contuse the walls of the channel sufficiently to prevent considerable oozing and not to lacerate or destroy.

One of my patients, a man of the 11th Hussars, was shot [illegible] so thin were they; but they ecrose, and the wounds were

But even in long flesh wounds in the extremities the same rapidity of repair was noticed. Here again the character of the injury influenced the result, for the walls of the track did not remain rigid, leaving a permeable tunnel. As soon as the passage had been accomplished the walls fell together, and thus further helped in the exclusion of air and in lessening the risks of sepsis.

Various suggestions have been made but have not been sustained that asepsis has been secured by the heat generated in the bullet itself—heat which it has been claimed is sufficient to destroy any pathogenic organisms. Cartridges carried in bandoliers were always exposed to contamination, but I have no doubt that the bullet received a thorough cleansing in the rifle. It was, of course, slightly larger than the bore and was forced to take the turn of the rifling by the explosion. The result was a certain polishing of the outer surface under immense pressure, and the after sources of contamination could only be found in passage through the air, the man's clothes, and his skin. Practically penetration was effected by a piece of clean very hard metal. Of course, there is no doubt that germs did gain access even under such circumstances, but in how many cases, even in operations under elaborate precautions, are they entirely absent? Unless the conditions which make them potent exist they give no trouble. The second cause was the early application of the first dressing. This was not always done by the surgeon. Very frequently the wounded man was able to attend to his own wants in this particular. Sometimes dressings had been lost and a piece of old linen or window-blind did duty. In spite of these, however, and of skin ingrained with dirt, the early closing of the apertures helped to avert mischief. But in the case of the extremities the bandages were of special importance in fixing the track of the wounds, in securing apposition of the walls, and in keeping the parts in that immobile condition which was of so much importance. The third cause was the climate. The temperature was high, the atmosphere very dry and particularly free from germs hostile to the surgeon's work. The general elevation of the plains in the northern part of Cape Colony, through Orange River Colony, and on to the Transvaal varied from 4000 to 6000 feet, higher by nearly 2000 feet than any mountain in the United Kingdom. The conditions, therefore, were exceedingly favourable. The intensely dry atmosphere quickly transformed oozing blood into crusts, and so helped on the healing in a wonderful way. In a moister climate the results probably would not have been as good, and we should have had to deal with a greatly increased number of cases of suppuration.

WOUNDS OF BONES.

So far we have been considering the effect of the small-bore bullet upon soft parts. Let me pass on to discuss the damage done to bones and the rate of mortality which followed. The subject is important, because in this as in all wars injuries of the upper and lower extremities outnumber many times those of any other part of the body. I will take a convenient illustration—the American Civil War. The total number of wounded treated in the [illegible] 71,694 were wounds of parts [illegible] unds of the upper extremities [illegible] 13. These produced fractures of bones in 32,992 and 27,274 respectively, or a total of 60,266. Injuries of bones, then, hold the first place in number, and hitherto they have been followed by an appalling mortality. It is in the damage inflicted upon these structures that we find the strongest evidence of the power of the small-bore. As the improvement in the rifle developed there was also an alteration in the shape of the bullet, which became elongated, and during these changes the character of the injuries to bones became correspondingly severe. The velocity at which the modern bullet travels as it leaves the muzzle may be taken as about 2000 feet a second, but during the flight this rate is gradually reduced owing to well-recognised causes. It is obvious that if the bullet within a few hundred yards after it has been fired strikes a bone it does so with crushing force, and that the severity of the injury decreases just in proportion to the distance which intervenes between the rifle and the object struck. In other words, the greater the velocity the greater the destruction when the bullet is suddenly obstructed by striking the shaft of a bone. Without entering into a discussion of the so-called explosive force produced on impact, what we find is that the bone is much comminuted and that fragments are carried some distance onwards in the soft parts as the bullet travels. But as the velocity lessens the effects are not so destructive; the bone is broken, sometimes into a few pieces, at the point at which it is struck, and sometimes the fracture has no subsidiary fragments. Occasionally a case is met with in which the velocity has been just enough to break the bone but not to carry the bullet through the limb after the collision. The behaviour of the bullet in the cancellous structure of the ends of bones differed from what I have just described. In the older forms of conical bullets with low velocity there was much tendency to lodge in these structures, but in this campaign the injury was chiefly a complete perforation. The different structure of the ends of bones as compared with the shafts accounted for this. The cancellous tissue presented a more or less elastic obstacle and yielded to the impact; but in the case of the shaft the hardness of the parts struck offered considerable resistance, and much of the force of impact was expended in breaking the denser obstruction into minute pieces.

AMPUTATIONS THROUGH THE THIGH.

In the campaigns of 40 or 50 years ago few injuries were more fatal than gunshot fractures of the femur, and the doctrine which had been laid down by earlier writers that amputation should be immediately performed still largely influenced practice. The flesh wounds were much more severe. Principles of cleanliness had not yet been formulated; the wounds always suppurated, and the result was a compound and comminuted fracture which often developed the worst forms of sepsis. It was to avoid these almost inevitable results that amputation was advised, for it got rid of a lacerated wound and fragments of bone and gave for a time a hope of safety. Nevertheless the mortality was appalling. Here are a few figures:—

Results of Amputation of the Thigh in Gunshot Fractures.

—	Cases.	Recovered.	Died.	Percentage of mortality.
Crimean war	2748	227	2033	73 5
American war (North) ...	6229	2839	3310	53 8
Franco-German war (German)	798	243	514	65·6
Franco-German war (French) . .	3794	342	3452	90·9

Out of a further group of 9017 cases 83 per cent. died.

But the results of conservative treatment did not show to much more advantage in the Crimea and the United States. I give the figures in the same campaigns by way of strict comparison.

Results of Conservative Treatment in Gunshot Fractures of the Thigh

—	Cases.	Recovered.	Died	Percentage of mortality.
Crimean war .. .	555	153	402	72·4
American war (North)	3467	1692	1684*	49·9
Franco-German war (German) . .	811	630	233	20 7
Franco-German war (French) –	866	811	55	9·4

* Result unknown in 91 cases

Nevertheless there was an improvement. The historians of the American Civil War hailed as victory the return which showed a mortality of 49·9 per cent. in conservative practice as compared with 53 8 for amputation. It was a gain of nearly 4 per cent. for the treatment which aimed at saving the limb

Then came the Franco-German war nearly 10 years later, and the lessons from America bore fruit. There was still a large number of surgeons whose opinion was valued who believed in immediate amputation, but even these yielded to the force of experience, and conservation as against amputation won by a difference of 26·9 per cent. The experience of France was remarkable, as only 85, or 9·4 per cent., are reported to have died without amputation, but the number given is so small that I am not prepared to accept it as representing the surgery of the period. Still the lesson remains that in those campaigns when the revolt against amputation began the result was with the progressives.

But if we turn to the recent Cuban war we have a further gratifying experience. Surgeon-General Sternberg reports that during the two years 1898–99 "82 cases of gunshot fracture of the femur were reported, six of which were treated by primary amputation and two by resection, the remaining 74 cases being treated by conservative methods, not because the conditions were not favourable for the performance of primary operations, but because of a conviction that under present methods of treatment the limb could be preserved without materially adding to the danger of life. The limb was lost through surgical intervention in only 7·3 per cent. of the cases. Of fracture of the upper third there were 32 cases, of which five were fatal under conservative methods; of the middle third, 27 cases and three deaths; of the lower third, 23 cases and one death. A general mortality of 10·8 per cent." This is a splendid record of the treatment of compound fractures of the femur in the field. I am not able to lay before you like figures from the campaign in South Africa. They have not yet been completely analysed, and partial results are apt to leave false impressions. Nevertheless, I think I may say that in no way have the number of amputations been so few, the number of limbs saved so many, or the mortality from such operations so small. Amputation of limbs was quite the exception and was only done when the case was otherwise beyond hope. For the lessons of modern surgery the vast possibilities of recovery which the teaching of Lister had put within the grasp of every practitioner of the art in the world had already proved that the nearer we could approach to natural conditions the greater was the safety for the patients. Therefore, when a bone was broken by a bullet and there was no other lesion but the track made through unimportant soft parts the indication was to apply an antiseptic dressing at once to secure as much immobility as possible and to have the patient sent to a place where rest and more deliberate attention could be had.

EXAMINATION OF WOUNDS.

The treatment of these cases in the first stage has led to some difference of views among surgeons, but I am satisfied that reason and experience point in one direction only. It has been recommended that fragments of bone which have been detached from the shaft ought to be removed and the limb then secured in splints. I am strongly of opinion that local examination ought not to be carried out unless the surgeon should be driven to it by developments. The fact that bone is broken can be elicited quite easily by the methods which we employ in a simple fracture. Of what value in treament on the field is it to learn whether there are four or 40 fragments? What should we learn by passing in probes or fingers except that there was fracture and that there were many pieces? To do this we should enlarge the wound considerably, introduce things that probably were not aseptic, disturb adhesions that were already in progress, break down clots, and generally do the things which were the very worst for the patient. It is surprising what little trouble many fragments apparently separated from sources of vitality may give. If they do necrose later they can be dealt with under safe conditions. But I am quite sure that, with rare exceptions, the wrong thing to do on the battle-field in a recent wound by a bullet involving fracture of a bone is to explore it with probes or to enlarge it for the passage of a finger and the removal of fragments.

WOUNDS OF JOINTS.

One of the interesting features of the surgery of the campaign was the injury done to joints. In a majority of cases the bone was more or less injured, but in three out of five cases of perforation of the knee-joint under my own care there was no apparent involvement of bone. Such cases did very well, most of them pursued an aseptic course, and recovered with good movement. Even suppuration did not demand more severe measures than incision and drainage. I have seen a bullet traverse the [illegible] astragalus with perfect movement [illegible] a naval officer the head of a pompom entered the astragalus and practically destroyed it, all that remained being the dense walls. There was a fracture of the tibia as well and the limb would certainly have been amputated under the old rules, but I succeeded in saving the foot, although with a stiff joint, and the patient is still in the service. Excisions again, were rare, and amputations were only performed on the field when vital parts were involved, or there was terrible destruction by a shell, whioh was an event of infrequent occurrence.

I have specially referred to injuries of the knee-joint because I wish to indicate how satisfactory our experience of them has been in this campaign as compared with that of 40 years ago. Then the doctrine was that when ever the knee-joint was penetrated by a bullet, whether the bone was fractured or not, the limb should be amputated, and the sooner the better. This view existed not only before the American war, but was emphasised by the experience then acquired. In the Crimea out of 138 cases 45 patients recovered and 93 died, or 67·3 per cent. In all but three of these there was fracture, of which the recoveries were 43 and the deaths 92. In the American war there were 793 cases, of which 402 were those of recovery and 376 were fatalities, or 48 per cent. In 659 instances there was fracture, of which 309 were recoveries and 350 fatalities. The proportion of cases in which bone was involved in wounds of the knee in the present campaign will perhaps be found to be somewhat less. But there can be no doubt that in spite of such a serious complication the cases did extremely well. The excisions must have been very few for I did not see or hear of any. The simple perforations were attended by some blood effusion, and, in my experience, trivial synovitis, and in these cases treatment by carefully occluding the openings and keeping the limb at rest was generally sufficient to secure safety and early restoration of normal movement.

PENETRATING WOUNDS OF THE ABDOMEN.

But the problem which most exercised the minds of surgeons in South Africa was the treatment of penetrating wounds of the abdomen. These had always been marked by the highest mortality in war. In the Crimea 92·5 per cent. of the British so injured died; 91·3 per cent. of the French. Here was a field in which there was plenty of scope for improvement. In the interval between that great campaign and the present far-reaching changes had taken place in the practice of surgery. It had been shown in civil practice that it was possible to deal with almost all kinds of pathological conditions within the abdomen. In our own country the surgery of this region had reached such a high level of security that many believed that the successes of the civil hospitals could be extended to the field of war, and that at all events the mortality would be diminished very effectively. The late Marion Sims had strenuously pleaded that these cases ought to be submitted to operation, because therein lay greater hope for the patient, and there were few surgeons who went to South Africa who did not hold the same view. In a few months, however, they abandoned that position, after experience of the actualities of war and the almost uniformly fatal results which followed —if they did not depend upon—interference. I think the causes of this were not far to seek. In civil life a patient so wounded is quickly brought into the best position for operation with all the appliances at hand which are almost essential to success. In warfare a wounded man may occasionally reach the field hospital within a short time, but when the casualties count into hundreds and thousands delay may extend into 12, and in some cases 24, hours before he is even rescued. Now, if there is an injury which should be treated promptly it is a lesion of the intestine; but the conditions in which operation should be done, if there is to be hope of success, are not to be found in a field hospital. The equipment is not sufficient or efficient and water is usually bad—in South Africa it was loaded with earth from which no filters could free it; it could not be boiled in sufficient quantity, and what we understand as the toilet of the abdomen was out of the question. There were, as I have hinted, two periods in which the surgical attitude towards these cases was quite different. In the early days many abdomens were opened, but probably all the recoveries after operation were less than a score. This depressing result has corroborated the experiences of surgeons elsewhere In the Tirah campaign five cases of laparotomy were reported, but the patients all died In the late Cuban war Senn says that in the four operation cases of which he personally knew the patients all died Surgeon General Sternberg of the United States Army, reports officially that in the two years 1898-99 they had 116 perforating wounds of the abdomen, of which 81, or 70 per cent., were fatal, and that of 10 cases in which laparotomy was performed nine patients died In South Africa I have known of a series of nine cases with one recovery Dr J E Neale, civil surgeon, has however, reported[1] a case of a man wounded at Frere, 15 inches of the intestine were resected and the patient never had a bad *symptom*

But, as I have said while the whole experience of operations was almost uniformly disappointing even in the most skilled hands, it was observed that many men with wounds of the abdomen did not present any alarming symptoms at all and that many of them quickly recovered Mr Watson Cheyne gives his impression, derived at Cape Town, that only 20 per cent of the abdominal cases had ended fatally; but this, of course, did not account for that large number killed outright or for those who lingered for a few days and died before they could be transferred to the base We are not yet in a position to deal with exact figures because they are not procurable, but I think it will be found that the proportion of deaths was far in excess of this, indeed, Mr Cheyne's subsequent experience at the front induced him to regard the death rate as much higher He reports 27 cases, of which 18 were fatal, two after operation, Mr Cheatle 10 cases of which nine were fatal From the Philippine war Dr Robinson has published figures which show 45 cases with a mortality of 48 9 per cent But of these eight were killed or died within 24 hours The interesting fact brought out, however, is that of 30 cases which were not operated upon only 10 were fatal, showing in this group a mortality of but 33 3 per cent These cases include all kinds of internal injuries, many of them necessarily mortal from hæmorrhage as in wounds of large vessels But if we limit our inquiry to wounds of the intestines we are still met by serious difficulties in settling the question of operation. Apart from the initial one of the unsuitable surroundings of the field hospital and the insecurity which must attend opening of the abdomen there, we must first try to determine whether the bowel has been wounded at all. If we accept the evidence of the apertures of entrance or exit there generally appears to be no doubt that the bullet has passed direct between the two points, and it seems impossible that the bowel has escaped perforation But there is abundant evidence, both recent and remote that bullets and even sharp weapons have traversed the abdomen not only without fatal results but without symptoms of perforation of the intestine I shall not trouble you with any other instances than that given by Mr Cheatle, and reported by Mr G H Makins in his admirable boo[illegible] of the War" There the bullet [illegible] and the sigmoid flexure but the [illegible] presented no indication of the slightest injury Even upon this one case it may be affirmed that a bullet can traverse the abdomen without wounding the intestine. I have seen or treated many cases in which the track of the bullet made it almost a certainty that it had passed through the bowel and in which the patient presented absolutely no symptoms up to his discharge from hospital Now here we have another problem Are we justified in opening the abdomen in such a case as soon as we see it with no other evidence than two external openings and a belief that the bowel cannot have escaped? There can be no doubt, I think, that after a prolonged search for wounds in the intestine which did not exist the patient's chances of recovery would be much on the wrong side

But I go further and take the cases in which there is actually a wound of the intestine Is it possible for recovery to take place? I am quite satisfied that in very many instances of this injury from the Mauser or Lee-Metford bullet the patients survived Some of them had bloody stools and other symptoms which made plain the nature of the lesion. Many reasons have been given for these remarkable escapes Probably they have depended in the first place on the angle of the impact of the bullet. A more or less direct hit would make a very small opening, which was immediately closed into a slit by contraction and in some degree blocked by mucous membrane The openings may have been further secured by pressure against an adjacent intestine, as suggested by Sir Frederick Treves, and kept secure until finally healed But if we go back to Mr Cheatle's case we find that there was no extravasation from the cæcum and no inflammation about the aperture, which had shaped itself into a minute slit If, however, the bullet struck at a smaller angle it would probably make multiple oval openings, with such loss of substance as to lead to extravasation and rapid infection of the peritoneum I have tried to show that there are cases in which there is no perforation, although we may suspect it, and cases in *which wounds occur which may run a safe course and in* which operation would only lead to greater risks There remains the group in which the wound does allow of extravasation and in which from various signs and symptoms we are able to recognise the condition. These cases as they stand are almost, but not quite, certain to prove fatal Can we do anything to diminish this tendency? I revert to the difficulty of operating upon them in a field hospital, and yet to send them back to a stationary hospital is almost hopeless They ought to be operated upon at once, but they are sent away with an infected peritoneum, which becomes worse each hour What chance is there for successful interference at the journey's end, when the patient is exhausted by pain and exposure and has been jolted in an ox-wagon for a couple of days? Yet if operation is to be done quickly there must be some better equipment of field hospitals and more suitable preparations for this special work for it is tedious and exacting and it demands expert hands and sound knowledge But every foresight will be nullified by the pressure of a severe engagement where there are many men to be attended to When everyone is working at high pressure night and day there is no time for the prolonged operations on the abdomen, unless it is possible to set apart one surgeon to deal with such cases only

On the whole, then considering the difficulty of diagnosis in many instances at the outset, the fact that intestines may be found unwounded and if wounded may be occluded by natural processes if not interfered with, it seems to me that in war as we stand at present the man whose abdomen is perforated by a small-bore *bullet has a better chance of life* without operation than with it, bearing in mind the circumstances under which laparotomy must be performed on the field That is an opinion which I think most surgeons came to when experience had ripened after the early months of the campaign Although the judgment may be a little humiliating it is one which must for the present be accepted

LODGED BULLETS

The war has developed once again the discussion upon the removal of bullets Formerly, with the low velocity the proportion of lodged bullets was much larger than it is now Some surgeons are of opinion that the missile ought to be searched for and removed at as early a moment as possible I think the practice in ordinary circumstances unjustifiable. If the nature of the wound enables us to reach the bullet without trouble or if it has lodged under the skin and can be reached by a simple incision it may be removed But remembering the character of the wounds made by the Mauser in most cases enlarging the apertures, or a search with probes or other instruments, may mean a suppurating instead of a non suppurating track It has been said in justification that the bullet may become displaced and give rise to troublesome after effects If these should occur the cause can then be dealt with but a bullet may lie buried with impunity throughout a long life Therefore, except under special circumstances which are sufficiently obvious, nothing should be done beyond trying to occlude the wound and to secure it from contamination

PROGRESS MADE BY MILITARY SURGERY.

I should have liked to speak of several other forms of injury, all of them full of interest, and of the great advantage given by the use of the x ray apparatus, but the limits of time demand that I should confine my remarks to some salient facts only The war is still in progress and it will take a considerable time after its conclusion before we can make an effective summing up But even thus far we have materials for conclusions which are not likely to be much modified We have seen a marvellous proportion of recoveries from severe wounds and we have been able to rejoice at the great reduction of suppurating cases and the practical absence of such infective diseases as tetanus, erysipelas, pyæmia, and hospital gangrene. This great difference in the records of to-day as compared with those of older and more bloody wars does not depend mainly upon the alteration in the bullet used. That, as we have seen, can do fearful things to a dense obstacle and add to its power for mischief by the laceration caused by bony fragments which it scatters on impact. To some extent the smallness of the canal made by it helps towards recovery. But, above all, the results are due to the treatment of the wounds by the surgeon and the operation of those great principles which have developed under the splendid genius of Lord Lister. He has made possible the nuquestionable triumph of conservative treatment. Honoured as he is throughout the whole world, proud as we all are to claim him as a compatriot, his most enduring memorial will be in the multitudes whom he has been the means of saving from pain and death, and in the direction which he has given to scientific surgery for all time.

---

[1] Brit Med Jour vol 1, 1900 p 604

When the recoveries from wounds in this war are made up and analysed it will be seen what a tremendous progress has been made in protecting the injured from disaster, even in the face of all the difficulties of the battlefield. For, while in the general and stationary hospitals the precautions necessary in modern surgery can be observed, it is, after all, at the initial stage that safety from sepsis is to be secured. "The fate of the wounded rests in the hands of the one who applies the first dressing," wrote Von Nussbaum, and the truth of this assertion has been proved every day. War is at all times full of horrors, but as it is waged to-day it is less terrible than before. In the recent Spanish-American conflict the mortality among the wounded dropped from the 12·96 per cent. of the Civil war to 6·64—a reduction of nearly one-half—a result in part no doubt due to the smaller bullet employed, but more certainly to the improved methods which have been established in the practice of surgery.

Our profession has taken its full share in the work in South Africa, and whether as officers of the Royal Army Medical Corps or as civil surgeons all have worked ceaselessly in ministering to the sick and wounded. They have not flinched in danger on the field and they have vied with their combatant fellows in deeds of valour. Six medical officers have been killed, nine have died from disease, and 12 have been wounded; three civil surgeons have been killed, 11 have died from disease, and five have been wounded. Of all branches, including orderlies and nurses, nearly 400 medical helpers have fallen victims to their labours. It is a noble record of devotion. We must always glory in it, but so also must we delight to know that the true spirit of patriotism is still with us and that so many of our profession have been ready to show, by rendering up their lives, that "A country's a thing men should die for at need."

An Address

ON

TUBERCLE BACILLI IN COWS' MILK AS A POSSIBLE SOURCE OF TUBERCULOUS DISEASE IN MAN.

Delivered at the Fourth General Meeting of the British Congress on Tuberculosis on July 25th,

BY PROFESSOR JOHN McFADYEAN, M.B. EDIN., M.R.C.V.S.

MR. PRESIDENT, LADIES, AND GENTLEMEN,—As recently as a few days ago, when I was mentally arranging the material for the paper which I have now the great honour of submitting to this Congress, I was under the impression that it would not be necessary to formally prove that the term "tuberculosis" as it is now employed by medical men and veterinary surgeons relates to one and the same disease. I thought that I might ask my audience to accept it as proved and generally admitted that tuberculosis in man is caused by a single definite species of organism—the tubercle bacillus; that this organism is also the cause of the disease to which veterinary surgeons apply the term "tuberculosis" in the case of cattle and other domesticated species; and that therefore there existed a *primâ-facie* case against the germs formed in the bodies of tuberculous animals as a possible source of tuberculous disease in human beings. To-day, however, the position of anyone who undertakes to discuss the intercommunicability of human and bovine tuberculosis is very different from what it would have been a week ago, for in the interval the greatest living authority on tuberculosis—the world-renowned discoverer of the tubercle bacillus and the man to whom we are mainly indebted for our knowledge of the cause of tuberculosis—has declared his conviction that human and bovine tuberculosis are practically two distinct diseases. I do not know how far the reasons assigned by Professor Koch for the opinion which he now holds on this question may have commended themselves to the members of this Congress, and I am overwhelmed at finding myself in a position which compels me to offer some criticism on the pronouncement of one "the latchet of whose shoes I am not worthy to unloose."

That bovine and human tuberculosis were identical diseases was generally supposed to have been finally determined by Professor Koch himself when he discovered that the human and the bovine lesions contained bacilli that were identical in morphological, tinctorial, and cultural characters, and showed that the artificial cultures from both sources produced indistinguishable effects when they were employed to infect a variety of animals. The labours of hundreds of workers during the succeeding 18 years produced nothing in serious conflict with the conclusion that human and bovine tuberculosis were identical diseases, but they brought to light what appeared to be additional evidence of this identity, such as the discovery that tuberculin produced a specific reaction in tuberculous cattle, whether human or bovine bacilli had been employed in its preparation. In short, the identity of the bacilli from the two sources appeared to be as firmly established as any other generally accepted opinion regarding the identity or non-identity of bacteria associated with disease in more than one species of animal. Since it thus appeared to be proved that the only difference between human and bovine tubercle bacilli lay in their accidentally different position—one being parasitic in man and the other in cattle—it was natural to conclude that when circumstances were favourable for the transference of bacilli from one species to the other human tuberculosis might have an animal origin, and *vice versâ.*

Opinions varied as to the frequency with which this transmission of tuberculosis from one species to the other occurred, but practically never within the last 18 years regarding the possibility and probability of such reciprocal infection. What are the grounds upon which we are asked to discard convictions that appeared to rest on such a solid basis? I shall endeavour to state them briefly, as I understand Professor Koch's train of reasoning. 1. The bacilli found in cases of bovine tuberculosis are much more virulent for cattle and other domestic quadrupeds than the bacilli found in cases of human tuberculosis. 2. This difference is so marked and so constant that it may be relied upon as a means of distinguishing the bacilli of bovine tuberculosis from those of the human disease, even assuming that the former may occasionally be found as a cause of disease in man. 3. If bovine bacilli are capable of causing disease in man there are abundant opportunities for the transference of the bacilli from the one species to the other, and cases of primary intestinal tuberculosis from the consumption of tuberculous milk ought to be of common occurrence. But post-mortem examination of human beings proves that cases of primary intestinal tuberculosis are extremely rare in man, and therefore it must be concluded that the human subject is immune against infection with the bovine bacilli, or is so slightly susceptible that it is not necessary to take any steps to counteract the risk of infection in this way.

Now, with the utmost diffidence I venture to submit that at least one of the premisses contained in this argument is not well founded, that the others have little or no bearing on the question, and that there still remain reasonable grounds for regarding tuberculous cow's milk as distinctly dangerous to human beings.

It cannot be denied that what may be called bovine tubercle bacilli are as a rule distinctly more virulent for cattle and other domesticated animals than are human bacilli or that the results of experiments indicate that in natural circumstances there is little danger of cattle becoming infected from human beings. But it cannot be admitted that the low virulence of human bacilli for cattle proves, or even makes it probable, that bovine bacilli have only a feeble pathogenic power for [illegible] to be probable if it had been [illegible] very virulent only for cattle, [illegible] hat these bacilli are highly dangerous for such diverse species as the rabbit, horse, dog, pig, and sheep, and, in short for almost every quadruped on which they have been tried, it appears to be highly probable that they are dangerous to man At any rate, it is impossible to cite any ascertained fact relating to other bacterial diseases that makes the contrary conclusion probable It is well known that the majority of the disease exciting bacteria are harmful to only one or two species, but all those that are common to all the domesticated animals are also pathogenic to man

With regard to the view that the difference between human and bovine bacilli in respect of virulence for cattle is of such a fixed and constant character that it may be relied upon to distinguish the one from the other it need only be said that that is very far from being proved It appears to be quite possible that what may be called the normal or average virulence of bovine bacilli for cattle may be reduced by passage through the human subject Besides there are very great differences in the virulence of tubercle bacilli found in animals of the same species and if a low degree of virulence for cattle is to be taken as *the distinguishing feature* of human bacilli there will be no difficulty in proving that the human disease is sometimes transmitted to the lower animals

The third proposition in Professor Koch's argument is the only one which is really germane to the point at issue—viz., that only cases of primary intestinal tuberculosis can possibly have had their origin in infected milk or meat and that "such cases are extremely rare" Professor Koch refers to several large series of post-mortem observations that appear to justify this statement and adds that he could have cited many more pointing to the same conclusion. Now, if it were a fact that all the statistics relating to this point were unanimous it would have to be admitted that primary intestinal tuberculosis is rare in the human subject, and that cases of infection through milk are still rarer, though even then it might be advisable to take measures to prevent the few cases But the statistics are not by any means unanimous and those that are likely to appeal with most force to the people in this country are not at all in accord with those quoted from Germany During the last few years the evidence obtainable from the post mortem records of two of the largest hospitals for children in this country have been analysed with great care in order to see what evidence they afforded as to the relative frequency of the different methods of infection in tuberculosis In the case of the Hospital for Sick Children in Great Ormond street this has been done by Dr G F Still and in the case of the Royal Hospital for Sick Children in Edinburgh by Dr T Shennan The conclusion at which Dr Still arrived was that in 29 1 per cent. of the cases of tuberculosis in children primary infection appeared to have taken place through the intestine. That is very far from being an insignificant proportion, and it is a striking fact that Dr Shennan arrived at an almost identical conclusion and estimated that 28 1 per cent of the cases of tuberculosis among children in Edinburgh were due to alimentary infection. There does not appear to be any ground for supposing that there is a large margin of error in these statistics, as the number of cases dealt with was considerable (547 in the two series) and in both series the post mortem appearances were interpreted in a way to which no exception can be taken In face of these statistics it is not possible to assent to the statement that cases of primary tuberculosis of the alimentary canal are extremely rare Precisely the contrary conclusion [illegible] e meanwhile be drawn with regard [illegible] his country—viz., that, at least in [illegible] by way of the alimentary canal is comparatively common. I therefore submit that there is still a strong *primâ facie* ca e against animal tuberculosis as a possible source of human tuberculosis and it becomes necessary to consider whether there are any data from which one may estimate the extent of the danger to which human beings are exposed through the occurrence of tubercle bacilli in milk.

The evidence in favour of the view that the ingestion of tuberculous milk is one of the causes of human tuberculosis includes a number of recorded cases in which the relationship of cause and effect appeared to be obvious From the nature of the circumstances evidence of this kind is very scanty, and it must be admitted that very few of the alleged examples are absolutely convincing Tuberculosis is a disease that develops slowly and assuming for the moment that tubercle bacilli do occur in milk and are a cause of disease in persons consuming such milk it is obvious that, as a rule the very act by which the infection is brought about destroys the only direct evidence of cause and effect that exists One could only expect to be able to trace the disease to the milk when, after the onset of symptoms pointing to infection by way of the mouth, the cow from which the milk had been obtained was still available for examination. In practice this is rarely the case, and it is therefore not surprising that medical literature contains very few specific instances of the infection of human beings with tuberculosis by means of milk It is obvious however, that the entire absence of evidence of this kind would in no way exonerate milk from the suspicion of being one of the causes of human tuberculosis

We have already seen that, at least in this country, in a considerable number of [illegible] life the first seeds of [illegible] the body by way of t [illegible] cases ought to be ascribed to tubercle infected milk? It scarcely appears to be possible to give a very confident reply *to this question, though some distinguished authorities* have not hesitated to express the opinion that practically all the cases of primary intestinal tuberculosis occurring in childhood may be set down to this cause The late Sir Richard Thorne, in [illegible] Control of Tubercul [illegible] his conviction that [illegible] tabes mesenterica in children, and he characterised the loss of child life from this [illegible] evidence on which this formidable [illegible] milch cow was of the followin. [illegible] r General's returns show that during the last 50 years there has been a marked decline in the death rate from human phthisis, which is the form that tuberculosis generally takes when the bacilli are inhaled On the other hand, during the same period there has been only a slight decline in the death rate at all ages from that form of tuberculosis which is ascribable to alimentary infection, and among children under one year of age there has been a notable increase in the mortality from that form of the disease The decline in the death rate from phthisis is ascribable to the great improvements which have been effected during the last 50 years in the hygiene of human habitations, such as improvements in lighting, drainage and ventilation These naturally, have not interfered with infection through milk which has therefore remained unchecked and in infants has even increased, because during the last 50 years cows milk has entered more largely into the dietary of very young children

There are several weak points in this argument Perhaps the weakest of all is the assumption that the deaths certified under the head of tabes mesenterica' correspond closely with those which the pathologist would classify as cases of primary alimentary infection. It is scarcely possible to doubt that the term tabes mesenterica ' in the Registrar General's return covers a heterogeneous collection of cases of which the majority may not be cases of tuberculosis at all But even if it is agreed to accept all the cases registered under the head of "tabes mesenterica as in tances of primary alimentary infection the figures found in the Registrar General s returns do not support the contention that milk is responsible for all the cases of tabes It is true that they indicate an increase in the death rate from alimentary tuberculosis among children under 12 months old, but on the other hand, there appears to have been a considerable decline in the death rate from the same cause at all ages between one and five years Now, if tuberculous milk were a frequent cau e of tuberculosis, one would not have expected the death rate from that cause to decline among children between one and five years of age, for there is no reason to suppo e that there has been any decline in the use of cows milk in the feeding of children at that age during the last 50 years The fact appears to be that the Registrar General s returns do not afford much trustworthy information with regard to the number of cases of primary alimentary tuberculosis and are absolutely worthless as an indication of the extent to which human beings are infected by means of milk.

There is another direction in which one may turn for evidence on this point We cannot with any pretence to accuracy ascertain the number of persons who annually become infected by milk, but we may be able to form some estimate of the existing danger in this connexion by collecting information as to the frequency with which milk contains tubercle bacilli. We know that about 30 per cent. of all the cows giving milk in this country are tuberculous in some degree. This statement, no doubt, indicates a deplorable state of affairs, but in the present connexion it is not quite so alarming as it at first sight appears. Fortunately, not every cow that is tuberculous gives milk containing tubercle bacilli. It is true that opinions with regard to this point are not absolutely unanimous, but there is ample evidence to justify the assertion that, as a rule, the milk is not dangerous until the udder itself becomes diseased. The experiments pointing to an opposite conclusion form only a small minority, and the results obtained in most of them were probably due to carelessness on the part of the experimenter. In a few of the cases in which the milk of an apparently healthy udder was found to be infective it is probable that the gland tissue was in reality diseased, though not to an extent discoverable without microscopic examination. The important question, therefore, is not what proportion of milch cows are tuberculous, but what proportion of them have tuberculous udders. Some authorities have estimated this to be as high as 10 per cent.; but the proportion is certainly much less than that in Great Britain. My own experience leads me to think that about 2 per cent. of the cows in the milking herds in this country are thus affected. Now, the milk secreted by a tuberculous udder always contains tubercle bacilli, and it sometimes contains enormous numbers of them, and when these facts are apprehended one begins to realise the seriousness of the danger to which, in the present state of affairs, those who drink uncooked milk are exposed. But there are one or two considerations that make the danger greater than the mere statement of the number of cows affected would at first sight indicate. In the first place, the udder disease is not attended by any pain or tenderness in milking, and the milk for a considerable time after the udder has become manifestly diseased may appear quite wholesome, though in reality it is charged with the germs of tuberculosis. It therefore often happens that the gravity of the condition is not realised by the milker or the owner of the cow, and the milk continues to be sold for human consumption. There is scarcely any room for doubt that if it were sold and consumed unmixed with other milk some of the persons partaking of it would become infected. In practice it is usually mixed with the milk from other cows that have healthy udders and thus the germs are distributed among a larger number of persons. Even tuberculous milk that has been thus much diluted may prove infective, but the danger to the individual consumer is in inverse proportion to the degree of dilution. Since about one cow in 50 is the subject of tuberculosis of the udder, and the average number of cows in the milking herds of this country is less than 50, it follows that the majority of dairies and farms supply milk that is free from tubercle bacilli, or at least does not contain any derived from this source On the other hand, when the infected material is present, it operates with the greatest intensity in the milk of single cows and in the mixed milk from small herds

It must be added that tuberculous disease of the udder is not the only source of tubercle bacilli found in milk. A great deal of the milk in the market contains a considerable quantity of dust and dirt, most of which comes from the cow's udder and the hands of the milker, and part from the dust of the air of the cowshed. When 30 per cent. of the cows in a byre are tuberculous the dirt in that building and the atmosphere in it are almost certain to contain tubercle bacilli, and some of these are very likely to find their way into the milk. The more dirt milk contains the greater is the chance that tubercle bacilli from that source may be present.

What has been said with regard to the extent of the danger to which the public are exposed through the sale of milk containing tubercle bacilli may be summed up as follows. The danger cannot be defined by stating how many persons are thus infected annually, or what fraction the persons thus infected form of the total number who contract tuberculosis in the course of a year At the same time, it is impossible to doubt that the danger is a very real one, since at the present time milk is a vehicle by which tubercle bacilli are often introduced into the bodies of human beings.

As to the means of averting the danger, the ideal method of counteracting this source of human disease would be to stamp out bovine tuberculosis or to prevent the sale of milk from every cow that is tuberculous. Unfortunately, it must be admitted that at present that is unattainable. At the present time probably not less than 30 per cent. of all the breeding and milking cattle in this country are in some degree affected with tuberculosis, and to urge that the disease should be attacked on the lines adopted in dealing with cattle-plague and pleuro-pneumonia is an effectual method of preventing any Government from touching the subject. But although the complete and rapid extermination of the disease is impossible it does not follow that nothing can be done, or ought to be done, in the way of prevention The disease has attained to its present alarming proportions simply because, until quite recently, altogether erroneous notions were held regarding its cause, and because there has hitherto been the most absolute neglect of the precautions necessary for its prevention. The greatest obstacle to successful action against tuberculosis, whether in man or animals, is the ignorance of the laity [illegible] the cause of the disease. The immense majority of [illegible] yet convinced that contagion is the only cause of tuberculosis, and very few of them have yet made the slightest effort to check the spread of the disease. As a rule, cows and other cattle visibly ill from tuberculosis are still left alive and in close association with their fellows, although the lowest grade of common sense and prudence would suggest that such animals ought to be promptly killed or at least isolated. It is not want of common sense, nor is it mainly lack of means, that is responsible for this reaction—it is simply a want of conviction on the part of cattle-owners that tuberculous animals are dangerous to their companions.

The first thing necessary in this connexion is education of the people regarding the nature of the disease. This is necessary, because in this country, where Parliament never moves except by the force of public opinion, the legislative action required will not be taken unless the people are satisfied of its wisdom and also because even the most drastic sanitary measures enforced by the law are likely to fail if they are not supplemented by the intelligent coöperation of the people The National Association for the Prevention of Consumption and other Forms of Tuberculosis and the Royal Agricultural Society have been endeavouring to disseminate sound views regarding the cause of bovine tuberculosis among farmers and others, but much remains to be done in this direction. But it is not reasonable to ask that things should be left as they are until the education of the farmer in the matter of tuberculosis has been finished. If there are any practicable and reasonable measures by which, figuratively speaking, the flow of tubercle bacilli from tuberculous cows to healthy human beings can be stopped or impeded, they ought to be immediately enforced.

As soon as the valuable diagnostic properties of tuberculin had been proved by experience it occurred to a good many people that its assistance ought to be called in in order to exclude tuberculous cows from milking herds. In other words, it was thought that although it might not be practicable to insist upon the application of the tuberculin test to all infected herds and to compel the isolation or slaughter of all cattle thus found to be infected, it might still be possible to require that only cows found to be free from the disease by the application of the test should be kept for milch purposes. I doubt whether anyone who is well acquainted with the circumstances of the case now believes this to be practicable. Here, again, the fact that one-third of the cows now giving milk are tuberculous is an insurmountable obstacle. The cost of carrying out the tuberculin test several times annually in all the milking herds in this country would be enormous, and the exclusion of all reacting cows from such herds would seriously disorganise cattle-breeding as well as milk production. Moreover, to rely blindly on the tuberculin test, and to pronounce the milk of every cow that does not react to it free from tubercle bacilli, would be very unsafe The test is recognised to be one of great value, but it is not infallible. Rather serious defects in connexion with it are: (1) that for a period after infection—a period that is sometimes very considerable—an animal will not react; (2) that in some advanced cases of tuberculosis no distinct reaction is obtainable; and (3) that in a considerable proportion of cases a second reaction is not obtainable for some days or weeks after the first. It is therefore clear that if we wish to exclude the milk of tuberculous cows, or if the object is the more restricted one of preventing the sale of milk from tuberculous udders, some system of inspection is necessary.

This was the conclusion at which the second Royal Commission on Tuberculosis arrived. We have already seen that whatever danger attaches to milk comes mainly from cows with tuberculosis of the udder, and the public health would be almost entirely safeguarded from this danger if we could exclude such animals from our dairies Periodical examination by competent inspectors would go a long way towards securing this object, but the inspection would require to be at rather short intervals, for tuberculosis of the udder may come into existence and attain most dangerous dimensions in a period of a few weeks. The more frequent the inspection the better, but of course this means a great deal of expense. If every town and rural district produced its own milk it would be a comparatively simple problem to organise and carry out a fairly efficient system of inspection of milch cows, but as the law at present stands the majority of the population cannot obtain this safeguard With the exception of Glasgow, Manchester, and a few other places, a local authority has no power to inspect cows outside its own district, and the helpless position in which this state of the law leaves the inhabitants of London and other large towns is obvious. If cows of which the milk is sold for human food had everywhere to be submitted to periodical inspection such inspection would naturally be undertaken by the various local authorities, each of which would supervise the cows and cowsheds in its own district; but the compulsory inspection of all the milch cows in the country would be a very large undertaking, and perhaps it would be premature to press for it. In the meantime a good case can be made out for making general the special powers relating to inspection of cows in outside districts which a few fortunate cities have acquired by special Acts of Parliament. This also was one of the directions in which the members of the second Royal Commission on Tuberculosis considered immediate action to be necessary.

There remain for consideration some other safeguards which would doubtless be less effective than those just discussed, but which, unlike these, would not be difficult to enforce—viz : (1) compulsory notification of udder disease and of any symptoms of tuberculosis in milch cows, with, of course, the power to inflict a considerable fine for not reporting; and (2) the interdiction of the sale of milk from any cow suffering from tuberculous disease of the udder or exhibiting clinical signs of tuberculosis. Against the demand for the amendment of the existing law to the extent of granting the public these very reasonable safeguards against infection through milk it cannot be urged that they would be very expensive or that they would press harshly on private interests. The present state of the law, or rather the almost entire absence of any law, dealing with tuberculous disease of the udder in cows is a scandal and a reproach to civilisation. It scarcely sounds credible, but it is a fact, that the owner of a cow in the most advanced state of tuberculosis, and exhibiting the most manifest signs of udder disease, may sell that cow's milk for human food as long as the sale has not been specially interdicted on the certificate of a veterinary surgeon, and that no penalty attaches to this crime of deliberately or carelessly placing on the market a food material charged with the germs of a dangerous disease. In the interests of public health the sale of milk from tuberculous udders and from cows that are obviously tuberculous in any part of the body must be stopped, and it must be declared illegal to keep such animals alive. There need be no hesitation in pressing for this reform because the measures demanded are in the interests of the owners of cattle and would be advisable even if it were established that bovine tuberculosis is not transmissible to man. There is no dispute as to the danger of visibly tuberculous animals to others of their own species, and it is the very reverse of a hardship to the owner of such animals to insist on their being slaughtered.

It would probably be regarded as a serious omission if I did not refer to one other method of counteracting whatever danger at present attaches to impure milk as a cause of tuberculosis. No matter how highly charged milk may be with tubercle bacilli, it can be deprived of all danger from that source by raising it to the temperature known to be fatal to these germs Less than the boiling temperature (212° F.) suffices for this purpose; but, unfortunately, the lowest temperature that can be relied upon imparts to the milk a flavour that many people find distasteful. That objection does not hold good in the case of infants and young children, and the custom of boiling or steaming the nursery milk for a few minutes cannot be made too general. But while abstinence from uncooked milk is a sure way of avoiding infection with bacilli present in that article of food, it cannot for a moment be admitted that this absolves public health authorities from all concern with the subject. Arsenical beer may be made harmless by adding the proper antidote before drinking it, but the most courageous brewer would not plead this as an excuse for selling the impure article.

In conclusion, I would venture to express the earnest hope that the Congress will not endorse the view that it is inadvisable to take any measures to prevent the transmission of tuberculosis from the lower animals to human beings. To justify the introduction of measures to that end it is not necessary to contend that this is a common method of infection, or that the danger arising from milk can for a moment be compared with that present in human sputum. The inhalation of tubercle bacilli expelled from the bodies of human patients is doubtless the great cause of human tuberculosis, and every practicable means of preventing infection in that way ought to be employed; but at the same time we ought not to concede to the milkmen the right to sell us tubercle bacilli, even if we were assured that —like Professor Koch's experimental pigs—we had nothing to fear beyond the development of "little nodules here and there in the lymphatic glands" of our necks and "a few grey tubercles" in our lungs

WHAT ADMINISTRATIVE MEASURES ARE NECESSARY FOR PREVENTING THE SALE TO THE PUBLIC OF TUBERCULOUS MEAT?[1]

BY SHIRLEY F. MURPHY, M.R.C.S. ENG., L.S.A.,
MEDICAL OFFICER OF HEALTH TO THE ADMINISTRATIVE COUNTY OF LONDON.

WHEN I was asked to open a discussion at this Congress on the administrative measures which are necessary for preventing the sale to the public of tuberculous meat it was at once obvious to me that no new material, no new fact, could be submitted to the meeting. The measures which are necessary are well understood by those who have directed their attention to the subject and what is wanted now is not the knowledge by such persons of what to do but the education of the public in the necessity for adopting in this country measures which have been tried and found successful elsewhere. In England we are always slow to modify our procedure and in any matter which is held to affect a trade interest especially slow, for this interest at once provides an opposing force which renders the education of the public difficult. This force is able to manifest its power from the beginning and at a time when the public concern themselves little with the subject. It is only at a later stage that the public find that they have an interest at stake and that they must bestir themselves to put law makers and law administrators in motion. When once this position is arrived at we may look forward to success. Our Congress may do much by discussion of this subject to create a wider interest in it and by influencing public opinion to bring about the result which is hoped for by those who see the need for better supervision over meat-supplies.

It is not within our province in this section to consider whether or not the consumption of the meat of tuberculous animals is prejudicial to man The title of the subject which I am invited to discuss implies that tuberculous meat must be excluded from the food-supply. This question has been considered by two Royal Commissions, the second of which was presided over by our chairman, Sir Herbert Maxwell. I shall later have to mention the conclusion at which this Commission arrived, and this because it has a necessary bearing upon the sort of administration which is needed, but I shall accept its conclusions and shall not enter into a discussion of pathological questions. I may, however, in commencement, briefly refer to the frequency with which tuberculous diseases affect cattle and the proportion of those which are slaughtered which must be deemed to be unfit for human food If animals were rarely affected with this disease, it might be difficult on this ground to claim the institution of an administration to prevent the sale of their meat to the public. This, however, is not the case, and it will suffice in evidence of this contention to quote the figures published by the first Royal Commission. This report shows that during a period of four years in the Copenhagen slaughter-house 17·7 per cent. of oxen and cows and 15·3 per cent. of swine were found to be tuberculous, and that in the Berlin slaughter-house in one year 15·1 per cent. of oxen and cows and 15·5 per cent. of swine were found to be tuberculous Of the oxen and cows in the Berlin slaughter-house 1·26 per cent. were condemned on account of tuberculosis and 0·23 per cent. of swine. The report further says that the Commission has reason for thinking that in this country "the facts about tuberculous animals would exhibit a broad resemblance to the foregoing if such records could be obtained." The figures obtained from public slaughter-houses in England are in no way conclusive of the amount of animals intended for food which are tuberculous or which are found to be unfit for human consumption. At the present time there is no need for the owner of an animal presenting signs of disease to have it slaughtered under conditions which would ensure its inspection. He can easily kill it elsewhere. I may state that among 18,440 cattle slaughtered in the Manchester public slaughter-house in 1896, 48½ carcasses of cows and three carcasses of bullocks were condemned on account of tuberculosis, or about 0·3 per cent., being but about one-quarter of the proportion condemned in the Berlin slaughter-house. Mr. James King, the veterinary inspector of Manchester, who supplied the figures relating to that city, stated to the second Commission that very few cows are sent to the public slaughter-house from the country round. "People," he said, "are a little frightened to send cows to the abattoirs. They do not care to send them in where there is rigorous inspection. The cows go [he thought] to the districts outside, because the Manchester market received a greater number of cows dressed than live cows coming to the abattoirs. The carcasses are brought in if it is thought they will pass in the Manchester market, and no doubt if they are badly diseased they are retained outside. That [he said] is my opinion about the matter." Mr. King is an officer of much experience, and his statements suffice to show that we must not assume that only one bovine animal in every three or four hundred is unfit for human consumption, for those entering the Manchester slaughter-house must be regarded as exclusive of a number which the owners believe to be too diseased to submit to inspection. It would be interesting to know what happens to those which are "retained outside," but for the moment I am concerned only to show that the proportion of cattle in this country which are tuberculous and which are unfit for human consumption is so large that if the public desire to avoid the consumption of their flesh they must provide an administrative system for the purpose. I may add the figures of another city to the above, taken also from the report of the second Commission. Dr. E. W. Hope, medical officer of health of Liverpool, stated that of 16,340 cattle slaughtered in the public slaughter-houses the carcasses of 214 were destroyed on account of tuberculosis—i.e., about 1·4 per cent., or about the same proportion as in Berlin In the two cities which I have referred to it has not been the practice to condemn the flesh of all animals which have suffered from tuberculous disease. In Manchester Mr. King stated that "if the disease is generalised the whole carcass is condemned; if it is only localised the localised part is removed and the remainder is passed." In Liverpool Dr. Hope said that if the disease were confined to the lung and the carcass generally was deteriorated then the carcass is seized, and it is also seized if the disease is very extensive and the carcass is not deteriorated.

---

[1] A paper communicated to the British Congress on Tuberculosis. Section I., State and Municipal.

I may now turn to the consideration of the amount of tuberculous disease which must be deemed to render the flesh of animals unfit for human consumption. Turning first to Germany, we find the practice is as follows. In Prussia the law of 1892 provides that (1) the flesh of tuberculous cattle is deemed unfit for food if it contains tubercle or if the tuberculous animal is emaciated, although there may be no tubercle in the flesh; and (2) that the flesh of tuberculous cattle may be considered fit for food if the animal is well nourished and (*a*) the tubercle is found solely in one organ, or (*b*) in the event of two or more organs being diseased these organs lie in the same cavity of the body and are directly connected with each other either through the lymph-vessels or through blood-vessels, which do not belong to the general circulation, but to the lungs and portal circulation. In Bavaria the law of 1892 provides that the flesh of cattle and swine shall be deemed fit for food if the tuberculosis is localised and in the first stage of development and the animal is in a well-nourished condition. The flesh is to be considered unfit for food if the animal is suffering from generalised and advanced tuberculosis and at the same time shows signs of emaciation. In Saxony the law of 1892 provides that the flesh of a tuberculous animal is to be deemed unfit for food (1) if the tuberculosis has so far developed as to lead to emaciation and if the flesh differs in appearance from that of healthy flesh; (2) also if the same is generalised—i.e., if the spread of the tuberculous processes in the body can have taken place only by the circulation of the blood (excepting the portal circulation) and at the same time emaciation exists in a high degree, or the meat, or the bones, or the lymph glands belonging thereto are impregnated with tubercle; and (3) also if the disease is in the form of a generalised miliary tuberculosis with fever. In France the law of 1888 prohibits the sale of the flesh of tuberculous animals—(1) if the lesions are generalised—i.e., not confined exclusively in the visceral organs and their lymphatic glands; and (2) if the lesions, although localised, have invaded the major portion of a viscus or show themselves by occurring on the walls of the thoracic or abdominal cavities.

The second Royal Commission recommended that the entire carcass and all the organs should be seized if (1) there is miliary tuberculosis of both lungs; (2) when tuberculous lesions are present in the pleura and peritoneum; (3) when tuberculous lesions are present in the muscular system or in the lymphatic glands, embedded in or between the muscles; and (4) when tuberculous lesions exist in any part of an emaciated carcass, and that the carcass, if otherwise healthy, shall not be condemned, but every part of it containing tuberculous lesions shall be seized (*a*) when the lesions are confined to the lungs and the thoracic lymphatic glands, (*b*) when the lesions are confined to the liver, (*o*) when the lesions are confined to the pharyngeal lymphatic glands, and (*d*) when the lesions are confined to any combination of the foregoing but are collectively small in extent In the case of the flesh of the pig it is recommended that, in view of the greater tendency to generalisation of tuberculosis in that animal, the presence of tuberculous deposit in any degree shall involve seizure of the whole carcass and of the organs.

If we may assume that it is necessary in the interest of the public health to enforce the requirements of these laws and recommendations—and I see no reason for any other view—we are obliged to consider the course which should be adopted for that purpose. The law in England as to meat inspection differs at the present time materially from that of other countries. In England the responsibility of determining whether the flesh of animals is fit or unfit for human food is cast upon the butcher. He is presumed to have sufficient knowledge for that purpose, and the duty which is cast upon the sanitary authority is to see that he exercises his judgment properly. If he is found offering for sale meat which is unfit for food he cannot claim ignorance as his excuse; his meat is seized and he is subjected to penalty. The alternative method, which is that adopted in other countries where there is systematic meat inspection, casts the duty of determining whether the meat is fit for human food on the local authority. The butcher brings to them the live animal which he is going to slaughter or the flesh of the slaughtered animal, and they determine whether or not it shall be sold for food While in England, therefore, meat is only occasionally inspected before sale in the countries referred to it is always inspected before sale. Which of these two methods is fairer to the public and to the butcher? Obviously it is impracticable to require all butchers to possess the knowledge which is implied in the regulations as to the meat of tuberculous animals which I have stated above, and, further, it is practically impossible to ensure that each of them will observe these regulations unless complete machinery is provided for this purpose. What then, have other countries done in this matter?

For what follows I am largely indebted to Professor Ostertag's excellent work on meat inspection. In Belgium the law of 1890 requires that all animals, including pigs, whose flesh, intestines, fat or blood is intended for human food, must be examined, after slaughtering, by an expert who is either appointed by the town or, if this does not occur, by the Government for the commune in which the slaughtering takes place, and the communes may require inspection of the animal before slaughter. The conditions under which this is to take place are prescribed by the commune which also bears the cost. The inspection is generally made by veterinary surgeons Inspection of the carcass and viscera must take place at the latest within 12 hours of the slaughtering in summer and 24 hours in winter, and the carcass must not be cut up before inspection. The abdominal viscera must be taken out before the arrival of the expert and so preserved that their connexion with the particular carcass can be recognised; in the case of solipeds, the thoracic viscera, the bronchial tubes, and the larynx must remain in their natural position. If after the examination the meat, viscera, &c., are found to be healthy the expert must stamp them with an approved stamp, in large animals on at least every quarter and in small animals on at least every half. If on examination the whole or part of the animal is considered to be unfit for food notice has to be given to the burgomaster who gives orders as to what shall be done with the carcass. If the owner of the animal is dissatisfied an appeal is provided. It is unlawful to sell meat which has been slaughtered contrarily to these regulations, and in the case of meat brought in from outside it is required that it shall only be the whole, or the half, or the quarter of the carcass, and the lungs must remain in their natural position; all must be examined and stamped. In Southern Germany, in part of Western and part of Central Germany, and in the free cities of Bremen, Lubeck, and Hamburg there is regulated meat inspection. Animals intended for human food must be examined before and after slaughter, in some places exemption being made for very young animals. In Northern Germany the conditions are not the same, obligatory meat inspection being required in some parts, including Berlin, and not in others, examination for trichinosis alone being practically general. In Brunswick and Saxony, since 1898, however, meat inspection is obligatory throughout, the law being very similar to that of Belgium.

In Sweden and Norway there have been laws requiring the provision of communal slaughter-houses since 1892 and since 1895 requiring meat inspection in the towns. Public slaughter-houses have, however, not been provided. In Norway there is at the present time, Dr. Bentzen informs me, only one public slaughter-house—viz., at Christiansund—and in Sweden, I learn from Dr. Linroth, there is no public slaug[illegible] Gott[illegible] Oste[illegible] houses and meat inspection in seven towns. In Austro-Hungary he says that the law requires the inspection of slaughtered animals, but the method of administration had prevented uniformity of action. In Italy he writes that a good scheme for meat inspection became law in 1890, but the regulation of meat being left to the provincial authorities has made a thorough reform impossible. The law requires the inspection of all animals intended for the food of man, the erection of public slaughter-houses in towns of more than 6000 inhabitants, and the stamping of meat, including the inspection of imported meat.

It is thus seen that already there is obligatory inspection of meat in some countries and that other countries are adopting the same course I am not exaggerating the position if I say that the trend of opinion and of law in civilised Europe is to require that meat intended for human food shall be inspected by competent persons before it is sold for this purpose. All countries are not equally advanced in this matter, delay being often caused by the want of provision of the one condition which is essential to the carrying out of this intention—the provision of public slaughter-houses. I need not point out the absolute necessity of this provision, if effect is to be given to the recommendations of the Royal Commission on Tuberculosis, or the requirements of laws which have been adopted in other countries. So long as animals may be slaughtered in numerous private premises in our cities inspection cannot be carried out. The inspector must be present at the time of slaughter so as to ensure that regulations as to what is to be deemed fit for food and what is to be deemed unfit for food shall be complied with and to prevent the dishonest butcher from practising those arts which give to meat a fictitious appearance and which are well known to those who have experience of meat inspection. This is becoming generally recognised, and in Prussia, Professor Ostertag tells us, public slaughter-houses have in the last 20 years "literally grown out of the earth," so much so that in 1897 there were 321 public slaughter-houses in that kingdom and 40 were provided in the period 1895–97. This provision is, of course, required for other reasons than those which relate only to the prevention of tuberculous disease in man; but we may here claim that it is absolutely necessary on the score of the disease which this Congress is especially considering. It is the want of public slaughter-houses which stands in the way of effect being given in some of the continental countries to their law of obligatory meat inspection; it is the opposition to public slaughter-houses on the part of the butchers which is the chief obstacle to the institution of a system of meat inspection in this country.

I may therefore briefly refer to the objections which have been urged by the butchers' trade to the replacement of private by public slaughter-houses. One of these objections is that the price of meat would be increased. The effect in Germany of the system of slaughter in public slaughter-houses and of meat inspection has been carefully considered by Osthoff who came to the conclusion in 1894 that the cost of the administration represented a sum less than about one-half of a farthing in the pound of meat. This is obviously a price of no practical importance when considered as a set-off against the advantage of the exclusion from sale for human food of meat which is unfit for the purpose. Dr. Schwartz, director of the town slaughter-house and cattle-market at Stolp, however, writing later, says: "The fear whether such establishments [public slaughter-houses] would pay or possibly cause an increase in the price of meat has been found to be quite groundless and has long been disproved. That this latter cannot be the case is conclusively proved by the experience of many years which individual communes possess; on the contrary, one may rather maintain that the prices have gone down, since the quality of the meat has improved, but the price has remained the same, apart from the general rise in the prices of food." It has also been urged that the meat killed in public slaughter-houses would be less well cared for than the meat killed in private slaughter-houses. Such argument would not be used by those alike familiar with the procedure in public slaughter-houses on the continent and of private slaughter-houses in this country. Compare for a moment the difference between the opportunity given for slaughter in a well-appointed slaughter-house fitted with every convenience and with cold chambers, to which the carcasses are removed, with the opportunity which exists in t[illegible] in the rear of private houses [illegible] urged that the offal which [illegible] be lost if the animal be slaughtered in a public slaughter-house. This, again, the experience of the public slaughter-houses of the continent shows, has no foundation. It has been urged that the butcher who has a private slaughter-house is able to employ his men at one time in slaughtering and at another time in his shop or calling for orders. There is no reason why, if the butcher prefers it, they should not be equally employed in the public slaughter-house as in the private slaughter-house It has been urged that if there were no private slaughter-houses there would be risk of a "ring" being formed to the detriment of the public. Obviously the best safeguard to the formation of a ring is to give to everyone selling meat the opportunity to slaughter his own animals. At the present time in London only a small proportion of meat vendors have this opportunity, and the rest depend, in the main, upon the middleman. They have no opportunity of slaughtering.

It has been said that the effect of the replacement of private by public slaughter-houses would tend to the exclusion from the meat market of English-grown cattle. Obviously so far as London is concerned the result would be the opposite, for every meat vendor would be able to purchase his own meat alive, instead of depending upon middlemen who may prefer to supply him with the meat of foreign animals I am satisfied that the use of the public slaughter-house is directly in the interest of the butcher who would save in expense and who would be able especially to save by using the meat-cooling chambers associated with it. I recently made some inquiry as to the cost incurred in London by London butchers in providing ice for their ice-safes in hot weather The amount is enormous and for this the public have eventually to pay in the price of the meat they purchase

It has been asserted that public slaughter-houses will be a charge upon the public purse This, again, is not in accord with continental experience At the time when the second Royal Commission on Tuberculosis was sitting several of its members, including its chairman, visited a number of public slaughter-houses on the continent and reported that "all the public slaughter-houses in Germany are self-supporting." A commission in Saxony, appointed in 1893, investigated the subject of the finances of public slaughter-houses. They reported that—

> As soon as the project [the establishment of a public slaughter-house] is mentioned—the butchers (the traders most interested therein) almost always oppose it, fearing various inconveniences to which their trade may be subjected in connexion with a public slaughter-house and its compulsory use, not the least of which is the stricter control of their business which comes with a [illegible] this, they raise the question of cost [illegible] an increase in the price of meat—a [illegible] public and with the representatives [illegible] opinion is not influenced by this opposition and by these fears of the butchers, and if the leading citizens are of opinion that a slaughter-house is necessary, the butchers almost always abandon their opposition [illegible] the citizen on his weakest side, the not inconsiderable cost of building, arrangement, and administration of a public slaughter-house is unduly brought forward by the butchers, and the prospect is held out of a heavy charge on the finances of the town, increased taxation, &c. It is important to emphasise that the establishment of a public slaughter-house is in no way prejudicial to the finances of a town or increases the taxes of the citizens, but that the funds devoted to the building and management are a very good investment. This the butchers' guilds and other persons who offer to [illegible] ow very well, and with this reason strive with [illegible], favourable financial project shall not escap[illegible] inancial matter the local authority has a predominant interest.

The Commission states that the receipts, without burdening the trader with heavy fees, provide, after payment of expenses, an interest of from 5 to 6 per cent. as well as a contribution to a sinking fund which will extinguish the debt in from 35 to 40 years.

I have dwelt upon this financial question at some length because only a few years ago London went through the first phase which the Saxon Commission describes. In England, therefore, we must, if we are to prevent the sale of tuberculous meat to the public, provide for and insist upon the slaughter of all animals intended for food in public slaughter-houses and we must provide competent meat inspectors for that purpose. The question has to be considered to whom shall this duty of meat inspection be entrusted. It is perfectly clear that the work must devolve upon those who have as a basis of the knowledge of meat inspection a knowledge of pathology, and this at once narrows the question down to the selection of members of one of the two professions having such knowledge—the medical and the veterinary. I do not think that in this country we shall ever relieve the medical officer of health of the duty of determining what is to be deemed fit for the food of man, nor is it desirable that this should be done; but in the actual carrying out of the work I believe we should do well to enlist much more than we have done in the past the services of members of the veterinary profession, and that we shall find that as they qualify themselves for this special duty they will be able to serve the purpose which we have in view.

In conclusion, then, I may say that the time has fully come when we should follow the excellent example which has been set us by other countries, that we should require all the animals which are killed in urban districts for human food to be slaughtered in public slaughter-houses, where there can be inspection before, at the time of, and after slaughter of the animal, that the meat shall be stamped, and that the public should be taught to look for this stamping as the test of wholesomeness rather than have to rely upon the pathological knowledge of the butcher and the housewife. Further, that all meat which has been killed outside a district, other than that which may have been killed in some public slaughter-house and which bears the evidence of inspection, shall be taken to meat-inspection stations for examination. Greater difficulty no doubt attends the inspection of meat in village communities, but even in such sparse populations the veterinary surgeon is to be found, and it is quite possible to organise a system by which his services are available when animals are killed for food. We are not now concerned with any question of other disease than tuberculosis, but I may refer to the enormous gain which it would be to the community to exclude from the human food-supply the meat of diseased animals which now can, practically without let or hindrance, find its way to the consumer. It would prevent, what has been within my own knowledge, meat from knackers' premises, being sent regularly to London from the provinces, and it would ensure to the poor people among us that in purchasing meat they were receiving the value of their money. It would, however, do much more than I have stated, and especially in respect of tuberculosis; for in closing the door to the ready disposal of the meat of tuberculous animals it would compel the stock-owner to take steps to prevent the infection of his herd and would lead to the earlier exclusion from the milk-supply of animals manifesting symptoms of tuberculosis, for the interest of the cow-owner would be to slaughter them before disease became advanced.

I beg to move:—

> That, in the opinion of this section, the meat of all animals intend for human food should be inspected before being sold for that purpo and that in all urban districts, and in all rural districts as far possible, such animals should be slaughtered in public slaughter house so as to ensure efficient inspection.

THE VETERINARY WORK DONE UNDE THE MILK CLAUSES IN MANCHESTER AND THE DIFFICULTIES MET WITH.[1]

BY J. S. LLOYD, M.R.C.V.S.,

LATE VETERINARY SURGEON TO THE SANITARY COMMITTEE, CITY OF MANCHESTER.

BETWEEN the dates Jan. 11th, 1900, and April 30th, 1901, the number of farms from which samples of mixed milk have been taken at the Manchester railway stations or *en route* to the city has been 401. Of these 259 are situate in Cheshire, and from 42 of these (or 16·21 per cent.) tuberculous milk has been sent to Manchester; 41 are situate in Staffordshire, from one of which (or 2·44 per cent.) tuberculous milk has been sent to Manchester; 93 are situate in Derbyshire, from four of which (or 4·3 per cent.) tuberculous milk has been sent to Manchester; whilst three are situate in Salop and five in Lancashire, all of which were free from tuberculous infection. From figures supplied by the farmers themselves to the public health office, the estimated number of cows kept at these 401 farms is 8408 or an average of nearly 21 cows per farm

The total number of farms from which tuberculous samples have been sent is 47 (or 11·72 per cent). At 31 of these 47 farms 35 cows with tuberculous udders have been found. At 15 of these farms no cows having diseased udders could be found, and subsequent control samples of the mixed milk from these farms have all been reported free from infection after being tested by Professor S. Delépine. In one instance the result of inoculation is undeclared. At most of these farms the owners have admitted selling cows from the farms between the date of the taking of the mixed sample at the station and the date of the visit of the veterinary surgeon, but only in two or three instances have the owners admitted that the cows sold were diseased, and in only one case has a farmer admitted that the cow had a diseased udder. In three of these instances the farmers stated that they also sent the milk from a neighbour's cows together with the milk from their own cows, and in two cases these were followed up, but with negative results. At the remaining one of the 47 farms samples of the milk from suspicious cows are still in process of examination.

To give the percentage of cows having tuberculous udders among the cows represented on the 401 farms from which the mixed milk sent into Manchester was tested it will be necessary to strike out the 15 farms at which no cows with tuberculous udders could be found and also the one farm from which the milk from suspicious cows is still under investigation. The average number of cows will then be represented by $\frac{31}{47}$ of $8408 = 5545$, which, taking 35 cows at the 31 farms, gives a percentage of 0·63.

The total number of cows clinically examined as the result of following tuberculous samples of mixed milk is 1308, but the number of cows examined irrespectively of previous samples of mixed milk is 4031. Of these 2182 were examined in the Manchester cowsheds, and among them eight cows were found to have tuberculous udders. This gives a percentage of 0·36. The remaining 1849 cows were examined in cowsheds outside Manchester, and among them nine were found to have tuberculous udders, equal to a percentage of 0·48 If we add up the number of cows thus, 5545 + 2182 + 1849, we have a grand total of 9576 cows the milk from which was tested for tuberculosis or among which cows with tuberculous udders were found by clinical examination; and by adding up the figures 35 + 8 + 9 we have a total of 52 such cows having tuberculous udders, which is equal to an average per- [illegible] for 1900 the number [illegible] alf in England was [illegible] f these to have tuberculous udders we have a total for England of 10,257. Or if we take the figures for Great Britain on the same basis—viz., 2,620,901 at 0·54 per cent.—we have a total of 14,152 cows with tuberculous udders. For administrative purposes the statistics will show a much lower proportion of tuberculous cows—viz., 35 out of 8408, or 9·4 per cent.

---

[1] A paper communicated to the British Congress on Tuberculo Section I., State and Municipal.

Regarding the disposal of the 52 cows mentioned, the particulars ascertained are as follows. Of the eight city cows having tuberculous udders, two are isolated and are still in the possession of their owners, who have promised to slaughter them ultimately in the presence of the veterinary surgeon. The remaining six have been slaughtered at the Water-street abattoirs; three of the carcasses were passed as fit for human food and three were condemned as quite unfit and were destroyed. Of the nine cows found outside the city, irrespectively of previously tuberculous mixed samples, [illegible] of the carcasses being passed [illegible] ther four, being totally unfit, [illegible] remaining four of these nine cows were disposed of by the owners and could not be traced. Of the 35 cows with tuberculous udders found by following up tuberculous samples of mixed milk, 15 have been slaughtered; three have been passed as fit for human food, two as partially fit, the unfit parts being destroyed; 10 have been condemned as unfit, four of which went to the knacker's yard, five were buried, and a portion of the other was subsequently discovered to have been sent into Manchester for human food. Of the remaining 20 out of the 35 seven are stated to have been fed and sold for slaughter, seven have been disposed of but have not been traced, and six are still in the possession of their owners. Four of these owners have promised ultimately to have their cows slaughtered in the presence of the veterinary surgeon. Thus out of these 52 cows with tuberculous udders only 26 have been definitely proved to have been slaughtered; the remainder, due to the absence of any compulsory power to deal with them, are either still in the possession of the farmers or have been sold by the latter, some it may be for slaughter, others probably to milk elsewhere. At any rate, nothing definite or trustworthy can be ascertained as to their ultimate disposal. It will thus be seen that against the successful working of the milk clauses certain difficulties have been found to arise, and I will now proceed to deal with each one shortly:—

I.—The first difficulty is where, on following up a tuberculous station (mixed) sample of milk to the farm, no cow is found exhibiting signs suspicious of tuberculosis.

1. In several instances where this has been the case the farmer has admitted selling cows from his farm between the date of inspection and the date of taking the sample. But, although in a few cases he has admitted that he had sold a diseased cow or a cow which he states has not been doing well, he has only in one instance admitted selling a cow which he knew to have a diseased udder.

2. Another possible difficulty which has been met with is where the farmer also sells milk from his neighbour's cows mixed with the milk from his own cows. In a few cases this has *come under my notice. In one case I failed to follow* this up, but in the remainder of the cases when followed up, I failed in each instance to discover a cow with a tuberculous udder. Still it is quite possible that contamination could be produced in that way.

3. Another reason for tuberculous infection in milk, and one which has been brought to the notice of the Council of the Royal Agricultural Society of England, is external and accidental contamination. It is possible, perhaps, that a consumptive herdsman or railway porter might infect the milk, but I think that it is not probable, and the committee appointed to consider the question by the Royal Agricultural Society of England did not attach any weight to this point. Another external source of contamination has been considered by Dr. J. Niven, and that is contamination by dirt in the cowshed. When we consider the dirty condition of some cowsheds and some cows, together with the fact that one of the cows may be suffering from tuberculous *muco-enteritis, it is quite conceivable that* the dirt on the cow's udder may convey to the milk the bacilli given off in the discharge from the bowels of the diseased cow or, it may be, from the matter coughed up by a cow suffering from pulmonary tuberculosis. Still, in these latter cases the presence of the diseased cow in the herd should not escape the notice of an observant veterinary surgeon. In all cases (19) where I have been unable to find the cow with the diseased udder at my first visit to the farm a control sample of the mixed milk from the cows on the farm has been taken for a second bacteriological examination by Professor Delépine In 15 of these cases the milk was reported as being incapable of producing tuberculosis, whilst in four instances the milk was still *found to be infected*, thus proving that the source of infection was still present. In these cases I again visited the farm, and in three cases, after a very lengthy examination both previously to and after having the whole herd milked, I have discovered a cow showing slight signs of disease about the udder, but in no one were the symptoms at all typical of tuberculosis. In each instance, however, a sample of milk from these cows was found when examined by Professor Delépine to contain tuberculous infection and to be capable of producing disease in test animals. The milk from suspicious cows on the other farm is still under investigation. That brings me to the next point—another reason why the cow with a diseased udder may not be found on the first visit of the veterinary surgeon to the farm.

4. There is sometimes a difficulty in diagnosis. Several authorities, including, I think, Professor Bang, have stated that a tuberculous cow can give tuberculous milk without having tuberculous disease of the udder. That is not my opinion. I can quite conceive that a cow with an udder apparently free from tuberculous disease can give tuberculous milk, but my experience with several such cows is that, if the cows are kept under observation for a short time (from one to three months) it will be found that the symptoms of the disease in the udder of the implicated cow will begin to be manifest. That has been my experience in other cases besides the above three In one case I took a sample of milk from a cow suffering from chronic pulmonary tuberculosis, the udder at the same time appearing healthy. That sample was examined by Professor Delépine, and he reported that it had caused tuberculosis in test animals. The cow was again examined by me in five weeks after the first examination, when I detected a slight atrophy of one hind quarter together with very slight induration of the same quarter. After consultation with Dr Niven and Professor Delépine I again examined the cow in a fortnight, when the induration was a little more pronounced I then took a separate sample of the milk from each teat, and these samples were examined by Professor Delépine He reported that the milk from the suspicious quarter only had caused *tuberculosis in test* animals I have also examined the udder of this cow on a subsequent occasion, when I found that the diseased quarter of the udder had become equal in size to the opposite healthy quarter In another case I have obtained tuberculous milk from a "wasting" cow but in this instance after the cow was milked a very slight hypertrophy of one half of the udder could be found but only by very careful manipulation and visual examination In several other cases I was only able to find the suspicious udder after the animal had been almost completely milked

The conditions and symptoms met with in cows suffering from tuberculosis of the udder differ very considerably, both *ante-mortem* and post-mortem In addition to the obscure cases just mentioned the symptoms presented in fairly well-marked cases differ very widely during life. For instance, I have met with a tuberculous udder in a two-year-old heifer, and several in four-year-olds, although the majority were in aged cows. Again, the bodily condition of the cow is no criterion, as I have discovered tuberculous udders in fat cows as well as in cows in fair condition and in "wasters." The condition of, or symptoms presented by, the diseased udder itself I have also found to vary considerably. As a rule, the disease is most frequently manifest in one or both of the hind-quarters of the udder, occasionally I have found it in the fore-quarters, and in several instances both quarters of the same side have been affected. In one case I found the disease very well marked *in the right hind-quarter and the* left fore-quarter, whilst the other two quarters were apparently free from the disease. Again, the diseased portion of the udder is generally hypertrophied, but in several instances I have found well-marked, really typical cases where a diseased quarter has been atrophied and where the secretory powers of the organ were to a greater or less extent destroyed, the milk being in most of these instances small in quantity and changed in appearance, the latter varying from thin normal-coloured milk to a mud-coloured liquid, and in a couple of instances to an amber-coloured serum. In all of those atrophied quarters the gland structure had been replaced by a hard tuberculous deposit, and they were also associated with the disease in at least one other quarter of the udder. In the amber-coloured serum mentioned above Professor Delépine found tubercle bacilli by microscopic examination.

In all cases of tuberculosis of the udder that I have met with I have been able to find some amount of hardening or induration. The amount has been very variable, as has been also the position or portion of the quarter affected. As a rule, the supra-posterior portion of the hind-quarter has been the seat of this induration, in most cases it has been fairly superficial, whilst in a few it has been more deeply seated, and in two or three instances I have found a small indurated mass only near the base of one of the hind teats, and placed either inward or forward to the ampulla of the teat. In the three instances where I was unable to find the cow with a diseased udder at my first visit to the farm I did not notice this induration, except at the second visit, and from this fact I conclude that this induration is subsequent by some weeks to the invasion of the udder by the tubercle bacilli, but that the milk from such an udder is infective before any sign can be detected, so as to contaminate the milk from an entire herd. In prosecutions under the milk clauses for failure to notify tuberculous udders, the question is usually asked by the defence as to the probability of the defendant knowing that his cow exhibited symptoms suspicious of tuberculosis of the udder. It is possible from the character of the induration to say if it has been of some standing. In more recent cases of tuberculous invasion of the udder, however, the nodular character of the induration is not so marked; it may appear of a granular character to a practised hand, often it is very diffuse, and if accompanied in that stage by little or no hypertrophy it is then easily confounded with what is termed a "fleshy udder." In these latter cases a milk-seller could hardly be expected to suspect tuberculosis and particularly, as is often the case, when the cow seems otherwise a healthy beast. But in these cases also he will often detect some change, and in order to protect himself he should seek the advice of his veterinary surgeon or notify the case to the proper authority and so keep himself within the law. Although the disease is usually chronic and unaccompanied by any acute symptoms I have in several instances met with cases where the disease has suddenly become acute, and from an old-standing disease in one quarter suddenly attacked the whole organ. In one case where a cow with a tuberculous udder has been isolated since January last I noticed on a recent visit (May 7th) that although the cow had calved in the meantime I could detect practically no alteration in the diseased quarter of the udder from what I had noticed when the cow was examined in December. There is still one other form in which I have found two cows suffering from tuberculosis of the udder, and that is where the udders were the seat of catarrhal mastitis of a tuberculous nature, and in the pus from which Professor Delépine found tubercle bacilli by microscopic examination. It should be added that other samples of a like nature were examined with a negative result. Before passing on to note shortly several conditions of the udder which may be confounded with tuberculosis I may point out that in all cases where I have found cows with tuberculous udders the diseased animals had all been in the possession of their respective owners for some considerable time, many of the country cows having been reared by the owners.

A very common condition met with in milking cows, particularly what may be called tied-up or stall-fed cows, is atrophy of one half of the udder, caused by continually lying upon one side only. The pressure of the cow's body forces the milk from the side of the udder next the ground, and the gland gradually becomes, to a variable extent, atrophied. This often gives the opposite half of the udder an enlarged appearance. A true hypertrophy of one part of the udder also follows a case of mammitis, where one or more quarters lose their functional activity, constituting lost quarters, and the other healthy quarters take on compensatory action and become hypertrophied. When these lost quarters waste completely away they are of no moment, except to depreciate the market value of the cow; but when the lost quarter is replaced by an indurated mass, as I have pointed out before, there is a possibility that they are tuberculous in that case; but then, in my experience, they have been accompanied by tuberculosis in one or more of the other quarters of the udder. Abnormal, but not pathological, hypertrophy of one or more quarters is also sometimes met with in milking cows, and especially is this so when supernumerary teats are present. But in all such cases, if the hypertrophy is of a non-tuberculous origin there has been an absence of chronic induration (with the exception of one which I will shortly describe) and the milk from the hypertrophied quarters of the udder has been non-infective when tested by inoculation into test animals. In all doubtful cases I have no hesitation in stating that I believe the inoculation test as carried out in Manchester to be absolutely infallible, and that it is as delicate as it is true, as proved in several cases to my knowledge where it has demonstrated tuberculous infection in both mixed milk and milk from special cows several weeks before the symptoms of the disease in the infected cow's udders became manifest.

The one condition of chronic induration which I have just mentioned is that caused by chronic interstitial mammitis. This affection of the udder is often a result of acute mammitis, but, according to the late Professor Walley, it may be interstitial in its character throughout. Owing to the amount of interstitial tissue formed the affected udder becomes indurated and often markedly hypertrophied. At the same time the secretory power of the glandular tissue is destroyed, and the milk secreted gradually becomes less and finally stops. Such a case I have had under observation for some time and a short account of it will, I think, be interesting. The subject is a Galloway cow about six years old, which was first seen by me in October, 1900. The animal had then been bought about a fortnight as a fresh calver. The right hind-quarter was a little hypertrophied and considerably indurated. I considered the case to be very suspicious and took a sample of the cow's milk. This was examined by Professor Delépine, and he reported that it had failed to cause tuberculosis in test animals. I again examined the cow at the end of November, when the condition of the udder was not materially changed and took another sample of her milk, which also was reported negative by Professor Delépine. Early in January, 1901, I again examined this cow's udder when I noticed that the induration seemed to be of a corded character, something like the feeling under the skin of an animal's trachea. With the owner's consent I tested the cow with tuberculin, when the animal passed the test. Samples of her milk were taken just previously to testing and again 12 hours later, also with a negative result. Just previously to testing the owner informed me that the cow was not giving so much milk from the indurated quarter as from the others—at first no diminution was noticed The quarter gradually became harder and more corded in character, at the same time that the quantity of milk secreted became less, and the quarter ultimately became dry.

II.—The second difficulty met with in working the milk clauses is failure on the part of the farmers and cow-keepers to notify to the medical officer of health the presence in their dairy of a cow "affected with, or suspected of, or exhibiting signs of tuberculosis of the udder," as required by sub-section 4.

III.—The third difficulty which has arisen in connexion with the working of the milk clauses in Manchester is due to the absence from them of any specific powers for dealing with cows suffering from tuberculosis of the udder after they have been found, and the tuberculous nature of the disease in their udders has been definitely proved. The procedure adopted by the medical officer of health in Manchester has been to advise immediate slaughter of cows which have been definitely proved to have tuberculous udders. In the case of exactly half of the 52 cows found to have diseased udders (26) this has been carried out. Six of the eight cows found in the city have been slaughtered at the Water-street abattoirs. The carcasses of these have been inspected by Mr. Holburn, the chief meat inspector, by whom three were passed as fit for human food and three were condemned as being unfit. The remaining 20 cows were slaughtered at different places in the country either in my presence or in that of Mr. Holburn. When the carcasses were inspected six were passed as fit for human food and 14 were condemned as being unfit. It may be noted that in several of these cases the animals were so far advanced with disease that the owners recognised the futility of trying to fatten them for the butcher, otherwise they would doubtless have been less easily advised to accede to immediate slaughter.

The *post-mortem conditions* that have been met with in the carcasses of those cov [illegible] been almost as varia [illegible] exhibited during life. [illegible] have been fit for humai [illegible] most of the latter car [illegible] have been very extensive, involving in addition to the udder and the mammary lymphatic glands most of the viscera and lymphatic glands, and in many cases tuberculous lesions, varying in age and extent, have been found on the serous membranes. In a few cases large patches of tuberculous ulceration have been found on the mucous membrane of the intestines. In other carcasses which were unfit for food the disease was not so extensive, but in these cases the carcasses were thin and wasted, so much so that the owners did not have the carcasses prepared for sale, but before slaughter decided either to bury them or to send them to the knacker's yard.

In two or three of the carcasses which were fit for human food, not only were they well-nourished but, excepting the udder and its lymphatic glands, very little tuberculous lesion was present, the carcasses being sold for from eight to 12 pounds. In all these cases, however, caseous deposits could be found in the mesenteric glands, although in one or two instances it required a careful examination of several of the glands in order to demonstrate the presence of the disease to the naked eye. In all cases of *tuberculous udder* the mammary lymphatic glands are found hypertrophied, but in many of the cases no tuberculous deposits are visible by microscopical examination, and it is only in animals that are thin, and where these glands are much enlarged, that the *condition can be detected during life.*

Regarding the disposal of the remaining 26 cows matters have not been at all satisfactory. Seven of the owners elected to isolate their cows with tuberculous udders, to stop selling their milk, gradually to dry off and to fatten them for slaughter. When the animals are not far advanced with disease this can, no doubt, be done to advantage; but in the interests of the public health these cows should not be sold except for slaughter and under adequate veterinary inspection. Where the carcass fulfils the conditions suggested by the Royal Commission on Tuberculosis and recommended by the Local Government Board there is no reason why such a carcass should be condemned, although it must be borne in mind that a cow with a tuberculous udder is in the majority of cases rather far advanced with disease, *and the longer she is kept for feeding purposes the more* advanced the disease will become, and the less likely that the carcass will be fit for human food. In all of these seven instances the owners were asked by the medical officer of health to inform him when they disposed of their diseased cows for slaughter, so that the killing of the animals could be verified and the carcasses inspected, but in no instance was this information given, although several gave a promise to do so. In 11 instances the diseased cows were removed from the farms by their respective owners and could not be traced Several of these cows were removed soon after my visit to the farms and after the diseased or suspicious condition of the cows' udders had been pointed out. In other cases the cows were removed as soon as the owners received the letter from the medical officer of health advising that the diseased cows should be slaughtered. In several of these cases no information regarding the disposal of the cow could be obtained; in others the owners wrote stating that the cows were sold for slaughter. In not one of such instances could the actual slaughter of the cow be verified, and in some of them it was afterwards ascertained that the buyers had sold the cows again in open market. It will thus be seen that 18 of these cows with tuberculous udders have been lost sight of, and as some of them were in calf it is quite probable that they may be giving diseased milk somewhere, possibly to be consumed in Manchester. Eight of the 26 cows are still in the possession of their owners; two of these are city cows and six belong to farmers in the country. The owners of all these have given either written or verbal promises to notify the medical officer of health as to the time when they dispose of these cows, so that their slaughter can be witnessed and the carcasses inspected.

THE RELATION OF ALCOHOLISM TO TUBERCULOSIS.[1]

BY T. N. KELYNACK, M.D. VICT., M.R.C.P. LOND.,
MEDICAL REGISTRAR, ROYAL INFIRMARY, MANCHESTER; ASSOCIATE OF THE OWENS COLLEGE, MANCHESTER.

ALCOHOLISM and tuberculosis stand foremost amongst the causes hampering human progress and limiting man's happiness. Through them the evolution of the race has been impeded, and, unfortunately, in spite of numerous restraining and restricting agencies, their baneful influence is still accountable for a high degree of mortality and an immense amount of sickness and suffering. The stay of such calamitous agencies has long afforded problems which have appealed to all sorts and conditions of men, and their solution even now is to a great extent shrouded in mystery and surrounded by difficulty. With two such morbid influences barring human advance it was but natural that eager minds studying the one should have been compelled to recognise the presence and action of the other. Hence the question as to the relationship of alcoholism to tuberculosis is one of old standing But since the answers have been hitherto by no means uniform it is particularly desirable that some approximation to the truth should be arrived at, and if possible generally accepted The position has been well expressed by Dr. J. F. Payne,[2] who says: "With regard to the influence of alcohol on the production of tubercle, the utmost divergence and, indeed, contradictory opposition of opinion prevails. Huss found tuberculous phthisis to be rare in drunkards, and that has been the general conclusion drawn from post-mortem observations. It has even been thought that drinking freely checks the progress of phthisis, but of this I can find little evidence. On the other hand, the more general impression is that alcoholism is a frequent cause of consumption." And Dr Payne goes on to say: "On this disputed point we must appeal to the methodised experience of those who have special opportunities of observation."

The subject, however, is one full of peculiar and unavoidable difficulties. And not the least arises from prejudices, which, however repugnant to scientific research, have only too frequently warped the minds of those who attempted an investigation of the matter. Efforts to elucidate the question by an appeal to what has been termed clinical statistics is necessarily permeated with fallacy. Purely experimental inquiry, however suggestive in the presence of modifying influences concerning which we have but little knowledge and but limited control, can afford but unreliable results. Mortality returns, although rendering material for interesting, and it may be useful, analysis, afford data too gross for anything but rough generalisations. A study by the pathological examination of a large number of cases would seem to afford the most hopeful method of research, and when combined with a discriminating clinical investigation is likely to accomplish as near an approach to the truth as we are likely to obtain under present *circumstances. But before indicating* the manner and results of such a method of inquiry it will be well to refer briefly to opinions and conclusions of certain authorities which, as the outcome of exceptional experience or special inquiry, may be deemed worthy of consideration; and it will be desirable that special reference be accorded to those expressions which are based on a knowledge of alcoholism and tuberculosis as they are met with more particularly in this country Three views are possible: (1) that alcoholism is antagonistic to tuberculosis; (2) that alcoholism bears no special relationship to tuberculosis; and (3) that alcoholism definitely predisposes to tuberculosis. Let us briefly consider them

1. *The view that alcoholism is antagonistic to tuberculosis* — Before the true nature of tuberculosis became apparent the opinion was somewhat widely held that habits of alcoholic excess were antagonistic to tuberculosis and even preventive. This impression still exists among a large section of the public and is apparently in part due to opinions expressed by many of the earlier writers on pulmonary tuberculosis. Indeed, in some medical quarters such a view is still held. This view

[2] Transactions of the Pathological Society of London, 1889, vol. xl. p 332.

was clearly expressed by Dr. R. Payne Cotton[3] many years since in his Fothergillian Essay: "It is worthy of remark that the habitual drunkard—he who is always in his cups—is not very often the subject of phthisis; such, at least, is the result of my own observations."

The idea that alcoholism was antagonistic to tuberculosis may, perhaps, in part account for the advocacy of its persistent and even excessive use in phthisis. Bennet,[4] writing some 30 years since, says: "Of late years in America alcohol, especially whisky, has been much lauded as a remedy in consumption"; but he adds: "I have seen a certain number of cases in which it had been long taken, but I cannot say with benefit. The daily ingestion of large quantities of nerve-stimulating, carbon-producing spirit certainly does not come under my ideas of hygienic treatment." Flint[5] used alcohol freely, that is from six ounces to a pint of spirit daily, and appears to have considered it beneficial, "but not in the sense of exerting a special influence upon the disease." Charteris, writing in 1877 concerning the administration of whisky to phthisical patients, says: "In private practice I order it to be taken *ad libitum.*" Dr. Hermann Weber[6] in 1885 was convinced of the great usefulness of alcohol in the treatment of phthisis. Dr. Thomas Harris[7] tried the effects of whisky containing 53 per cent. of alcohol during a period of nine months. 26 cases were so treated, the doses commencing with two drachms of pure whisky gradually increased up to one and a half ounces of whisky every four hours, day and night. Dr. A. Ransome, who saw many of the cases, expresses the opinion that "at certain times of the day the dose of alcohol was unnecessarily large—for some of the patients at times were distinctly flushed and slept heavily even in the daytime." Dr. Harris states: "No case left the hospital in a worse state than that in which he entered it. As regards the physical signs, very little difference could be detected between those at the date of admission and the date of the discharge of the individual." Manifestly in no instance did "cure" occur.

Reference has frequently been made to Stokes's account of a gentleman who recovered from pulmonary tuberculosis after regularly drinking "seven tumblers of punch every night," but it is sometimes forgotten that at the same time he was duck-shooting every day that he could go out, and according to his own account "had to stand up to my hips in the Shannon for four and five hours of a winter's day following the birds."[8]

It is interesting to note that Bell of New York as far back as 1859 opposed the current view, for he then stated: "The opinion so largely prevailing as to the effects of the uses of alcoholic liquors—viz., that they have a marked influence in preventing the deposition of tubercle—is destitute of any solid foundation. On the contrary, their use appears rather to predispose to tubercular deposition. When tubercle already exists alcohol has no obvious effect in modifying the usual course it takes. Neither does it mitigate in any considerable degree the morbid effects of tubercle upon the system in any stage of the disease."[9] The abolition of alcohol from many modern sanatoria seems to indicate that, as Dr. Ransome well expresses it, "owing to the terrible consequences of excess and to the proclivity of mankind to its excessive employment it [alcohol] can only be recommended in selected cases with many cautions."[10]

2. *The view that alcoholism bears no special relationship to tuberculosis.*—Many hold that alcoholism bears no special relationship to tuberculosis and only exerts an indirect influence in so far as it leads to lowering of general vitality and places the individual under conditions particularly favourable to the infection of tubercle. And certainly the circumstances attending the life of the chronic alcoholic are generally such as to specially expose him to the risks of tuberculosis. His habits lead in great measure to an indoor existence, the maintenance of an insanitary environment, insufficiency of suitable food, oftentimes to the influence of depressing emotions, and not infrequently his indulgence necessitates his following an occ [illegible] peculiarly inimical to h[illegible] neglect, uncleanliness, [illegible] cannot be overlooked, [illegible] any attempt to estimate the effect of alcohol *per se* in rendering the tissues peculiarly vulnerable to the tubercle bacillus [illegible]

3. *The view that a[illegible] tuberculosis.*—The view [illegible] to tuberculosis has of r[illegible] Indeed, the tendency of modern opinion is to recognise alcohol as an agent which renders the tissues specially [illegible] to tuberculous infection. This [illegible] recent expressions as the followi[illegible] a recent article on Tuberculosis [illegible] must be regarded as a powerful [illegible]culosis. ... It is almost invariabl[illegible] the lungs in patients dying in the course of alcoholic paralysis. ... Tubercle of the peritoneum or pleura frequently complicates cirrhosis of the liver.' ... Alcohol in excess undermines the strongest constitutions and renders the body less resistant to diseases of all kinds. This is especially true when the individual leads a sedentary town life. Considerable amounts of alcohol may be taken without obvious deterioration of health by persons who lead an out-of-door life and eat heartil[illegible]s appear to be specially liable to ac[illegible]

One of the most [illegible]onouncements is that of Professor Thomas Oliver, who says: "Nor is there any truth in the opinion held by the laity that the use of alcohol protects the individual against tuberculous disease. I do not refer to such a restrictive employment of alcohol as a glass of beer or stout or a little wine at dinner-time; that may be helpful to the individual. It is to the mistaken opinion that where there is a [illegible] to the disease it is necessary to be [illegible] In my experience of young men with a hereditary tendency to phthisis alcohol has, by the late hours which it encourages and the careless and irregular habits that it fosters, frequently precipitated the individual into active tuberculous disease, which abstinence and more careful living would have assuredly prevented. It indirectly favours the development of tuberculous disease." Pulmonary tuberculosis was found by Dickinson to be more frequent in drinkers than in ordinary people in the proportion of three to one. Dr. H. D. Rolleston, quoting Dr. H. Mackenzie, states that in 67 cases of pulmonary tuberculosis occurring in drinkers a family history of tubercle was only found in 10, whereas it is found in about 30 per cent. of the ordinary cases. The frequent association of pulmonary tuberculosis with alcoholic peripheral neuritis and its presence, too, in nearly one-third of the cases of cirrhosis of the liver are circumstances which show that under the debilitating influences of alcohol resistance is reduced, ordinary pulmonary catarrhs are not so quickly thrown off, and thus the bacillus of tubercle gains an easier entrance. Some have held that there is a tendency for phthisis in alcoholics to assume the fibroid form, but this is not in accordance with the best modern experience. Dr. G. V. Poore and Dr. W. H. Allchin in a recent article[13] speak of the association of tuberculous phthisis with alcoholic cirrhosis of the liver as "well established, the course of the disease being usually one of rapid caseation and excavation with broncho-pneumonia and rarely towards fibrosis." But the close association of tuberculosis and alcoholism has now been widely recognised not only by British physicians but also particularly by Americans and French observers.

Various suggestions have been made in explaining the liability of alcoholics to tuberculosis. There can be no doubt but that the non-hygienic surroundings and nutritional impairment and lowered vitality of the drunkard greatly predispose him to tuberculous invasion. But it is contended by some that even besides these factors there are special influences arising from the action of the alcohol and its associates. Professor Sims Woodhead has recently shown that alcohol has a marked influence in altering, or determining alteration of, the cells of animals subjected to the action of certain pathogenic organisms. Professor Abbott of Pennsylvania and also Dr. Deléarde working in the Institut Pasteur at Lille have recently shown that alcoholised animals are more readily infected by many organisms than non-alcoholised animals and other investigators have also shown that alcohol produces a marked negative chemiotaxis. It has also been found that animals brought into a state of chronic alcoholism are much less readily rendered experimentally immune to microbial infection. Attempts have also been made to show that alcohol through its influence on nervous structures renders the tissues and especially the lungs prone to invasion by tubercle.[14]

In order to compare some of our Manchester experience with the views and opinions above indicated I have endeavoured to analyse and to express the results of observation of hospital ca [illegible] nce to pathological data [illegible] sis for the formation [illegible] of alcoholism and tuberculosis.

1. *Alcoholic neuritis and phthisis.*—Some time since I analysed a number of fatal cases of peripheral neuritis occurring in chronic [illegible] to pathological exan [illegible] They formed 1·6 per [illegible] during that period. [illegible] seven. This gives a percentage of over 57. All the cases were females. In only one subject were there distinct tuberculous lesions elsewhere than in the lungs, and then [illegible] In one subject there was [illegible] the apex of the lung, but it [illegible] phthisis was rather due to *a fresh infection than from this latent patch.* In five cases both lungs were more or less involved. In two the left was the only one show [illegible] process. In three of the cases [illegible] n rapid. In four it seemed t [illegible] onths. One subject, it was st [illegible] months before her death. In one case one lung only was studded with small tubercles, the injection having been recent. In two there was more or less extensive caseation. Four presented evidences of softening and cavitation, and in two of these there was some fibrosis. Since collecting the above[15] I have gone over my more recent pathological notes. Two further [illegible] to necropsy [illegible] the subject [illegible] recent tubercles. There was no softening, but caseous foci at the apices were apparently of older formation than the tubercles elsewhere. In the other case, a female, aged 32 years, in whom there was also a fatty and cirrhotic liver, the lungs, [illegible] patches of [illegible] of tubercle. [illegible] nine female [illegible] subjects of [illegible]

In connexion with the recent remarkable outbreak of arsenical neuritis in Manchester and district, and occurring principally in alcoholics among the poorer classes, it is interesting to note that in a considerable number of the fatal cases active pulmonary tuberculosis was present and in some undoubtedly it had hastened the end.

2. *Tuberculosis is also of frequent occurrence in the subjects of alcoholic cirrhosis of the liver.*—In many cases it is manifestly of the nature of a terminal infection. In order to throw light on this matter the records of 3053 medical cases examined in the pathological department of the Manchester Royal Infirmary [illegible] 121 examples of commo [illegible] and complicated cases w [illegible] cardiac or such chronic affection as seemed to have led to secondary changes in the liver were excluded. All examples of "biliary" cirrhosis and those in any way connected with syphilis have been passed over. After omitting several doubtful cases, in 28 tuberculosis, either active, latent, or obsolete, was present. Thus, over 25 per cent. presented evidences of tuberculosis, active phthisis was present in 14 (12 males and two females), and active peritoneal tuberculosis in 12 (nine males and three females). Of these, six males and one female had involvement of both lungs and peritoneum. In five males and one female the lungs alone were affected, and in two males and two females the peritoneum alone. No less than 12, or nearly 10 per cent. of the 121 cases, appeared to die directly from tuberculosis. The average age of those in which active tuberculosis was limited to the peritoneum was nearly 47 years. The average age of those in which active tuberculosis was limited to the lungs was just over 44 years.[16]

LEGISLATION SUGGESTED FOR CONTROLLING AND ERADICATING TUBERCULOSIS IN ANIMALS.[1]

BY PROFESSOR DUNCAN McEACHRAN.

DELEGATE TO THE CONGRESS OF THE CANADIAN GOVERNMENT.

THE subject for discussion which I have the privilege of introducing must be carefully considered in all its various bearings, lest by proposing impracticable enactments we nullify our good intentions and give rise (as has already been the case in some countries and states) to bitter opposition by the owners of infected herds. Our efforts must be to educate the people so that they themselves will voluntarily adopt our suggestions, and, with the assistance of the State, to bring about a gradual diminution in the numbers of tuberculous animals in our herds, and the adoption by every stock-owner in the land of thorough preventive measures by which its re-introduction will be rendered impossible. The first step, therefore, which I would recommend is the publication and distribution among the masses—the agricultural population in particular—of information on the subject of tuberculosis. Much good work has already been done in this direction, but more must be done. If we look back for 35 years, when Villimin, Viseur, Chauveau, Gerlach, and others were engaged in demonstrating the contagious character and transmissibility of this disease, and compare our scanty knowledge then with the vast amount of information which, thanks to Koch, Bang, Nocard, and many others, we now possess, it will be easily understood why we who have been in the field of active work in the practical sense, as practitioners and advisers of our Governments, have in early days hesitated to advise active measures of control or eradication, and why the Governments have been slow to pass enactments bearing on the subject.

It was in 1882 that Koch first communicated the results of his investigations of the etiology of tuberculosis before the Physiological Society of Berlin, followed by further communic [illegible] transmissibility being [illegible] vestigation and experi [illegible] butions to the literature of tuberculosis have for many years filled our journals and bookshelves to such an extent that no excuse is left for ignorance concerning the subject on the part of those interested in it. In citing evidence in support of any suggestions one may make as to legislation necessary to enable the people, assisted by the Governments, to control and subsequently to eradicate tuberculosis from the lower animals, we necessarily must consider the measures tried by those countries, especially in Europe and America, which have dealt with it. It is to be hoped that in the course of the discussion some new practical suggestions will be adduced which this Congress can recommend for adoption. Until Koch demonstrated that tuberculosis was due to the invasion of an organism, the tubercle bacillus, communicated either directly from an infected person or animal or by intermediate sources of infection, especially by buildings, pathologists were content to attribute its existence and extension to heredity; when, however, its real nature and its pronounced contagious character came to be known, both medical and veterinary practitioners stood aghast in contemplation of the thousand-and-one blunders which crowded their memories consequent on want of this knowledge. I remember well when, 30 years ago, I had temerity enough to read a paper based on the continental investigations referred to, before the Medico-Chirurgical Society of Montreal, in which I ventured to say: "*The experiments of continental* investigators have clearly established the close relationship between tuberculosis in men and in animals and the possibility of the disease being in many ways transmitted from the one to the other; and I am well aware that this disease is far more prevalent in the dairy herds supplying milk to the citizens of Montreal than is generally known, therefore I feel it my duty to invoke the aid of this society in endeavouring to bring about certain sanitary improvements in connexion with our meat- and milk-supply by the establishment of abattoirs under proper inspection, supervision of dairies, and inspection of milk." Such was the limited information on these matters at that date that of about 40 members present only one was in sympathy with the statements made. He was at the time a young man but recently graduated who has since made his mark in the world of medical science—I refer to Professor William Osler of Johns Hopkins Hospital, Baltimore. He alone would admit even the probability of contagion, or intercommunicability from animals to mankind or from mankind to animals—a doctrine which was to sweep away the long-cherished belief in heredity as a sole cause.

[1] A paper communicated to the British Congress on Tuberculosis. Section IV., Veterinary Tuberculosis in Animals.

Pursuing this subject by close observation and numerous investigations of herds in Canada in which the disease existed instance after instance came to my knowledge of cases where the infecting animal was clearly traced to a diseased herd. Valuable herds were destroyed by tuberculosis and several owners were brought to the verge of ruin. At the period to which I refer shorthorn cattle (Bates and Booth families) had attained fabulous values, £5000 being a common price for a Duchess heifer, one cow being sold for nearly £9000 in the State of New York. Many of them were tuberculous. The frequent discovery by clinical examination of cattle imported from Britain passing through our quarantines, tuberculosis not being legally classified as a contagious disease at that time, obliged me to urge on the Government the necessity of amending the Animals Contagious Diseases Act so as to include tuberculosis in the list of contagious diseases. This was done in 1886, thus enabling us to put a stop to such dangerous animals being admitted to the country to the serious detriment of our home herds Members of my own profession, and of the medical profession, did not hesitate to say that this act was premature owing to the etiology of the disease being not then sufficiently understood. Were proofs wanting of its contagiousness, I could furnish sufficient to convince the most sceptical, but I should be wasting your time by their recital. I must, however, crave your indulgence for a few minutes while I make some general allusions to this characteristic of the disease.

The infection of healthy animals we know takes place readily from cohabitation, the bacilli gaining entrance by the respiratory organs in most cases · but by the digestive tract in many, especially in calves when suckled by diseased mothers, and calves, pigs, and other animals fed on milk or on dairy by-products containing living bacilli—in pigs when allowed to eat tuberculous matter found in carcasses and slaughter-house refuse given them as food; probably, too, in rare instances, from eating the flesh of tuberculous animals. It is to the buildings themselves, however, that we must look for the chief source of infection, and to neglect of disinfection and sanitation must we attribute in a great measure the continuance of the disease and re-infections with which we are familiar. I could cite repeated instances of herds cleared out and new purchases made, with every care in purchasing, being followed by new cases of tuberculosis; so that I feel that too much trouble cannot be taken by practitioners who are employed to eradicate this disease to make sure that the buildings are aseptic and that sufficient air-space is provided as well as a rational system of ventilation, whereby pure air is admitted and foul air driven out, also that properly trapped drains carry off the liquid excrements and prevent the return of noxious vapours. The importance of pure air and sunshine cannot be overstated in considering the prevention of tuberculosis. It is, however, a mistake to suppose that infection will not take place when diseased and healthy cattle are brought together, even when these conditions exist in the very highest degree. I have seen tuberculosis prevalent in ranche cattle, few of which were ever under a roof, ranging on the foothills of the Rocky Mountains in Montana. I have known a valuable herd of Polled Angus which were brought into the Peace River country in the far North-west of Canada which proved to be tuberculous and was ultimately exterminated in consequence. In these and other instances which might be referred to pure air and sunshine certainly prevailed, yet these did not prevent infection from taking place when the animals were congregated in corrals, bunched together during fly-time, or placed in infected sheds in winter.

Heredity.—To eliminate heredity entirely from the causative faculty would be an error; but we are safe in saying that it plays a very unimportant part in its extension. The rarity of the disease being found in calves at birth in all countries has been noticed by Professor Bang, Professor Siedamgrotzky, and others, and the immense success attending the rearing of calves from tuberculous cows by Professor Bang's system in Denmark and other countries, including Canada, proves conclusively that it is not hereditary in the same sense as gout or insanity are known to be transmitted from parent to progeny. When visiting Professor Bang at Copenhagen three years ago he showed me two newly-born calves sent in by an inspector; in the livers of both tubercles were found. Uterine tuberculosis when seen is generally associated with generalised miliary tuberculosis, especially when it is peritoneal. The rarity of tuberculosis in the male genital organs precludes the probability of infection by copulation, except in very rare instances; hence we infer that when the newly-born calf is found tuberculous infection has probably taken place within a diseased uterus. By far the most numerous infections have occurred after birth. Professor Bang says: "I had occasion to observe more than 400 cases of tuberculosis either in fœtuses or newly-born calves; nevertheless, the number of congenital tuberculosis has scarcely gone beyond 0·33 per cent. of the killed calves even in the most infected regions" While intra-uterine infection from a diseased mother is occasionally seen congenital tuberculosis plays a very unimportant part in the continuance and extension of the disease compared with the many ways in which the essential factor in its production—viz., the tubercle bacillus—gains an entrance to the animal body; in other words tuberculosis is a contagious disease, not a hereditary one as was supposed

The diagnosis of tuberculosis—The clinical diagnosis of tuberculosis, even by the most expert clinical examiner, except in advanced cases, is always unreliable, as tubercle may exist in such a stage as would be impossible of diagnosis by this means.

The tuberculin test.—The discovery by Koch, in 1890, of the production of fever, indicated by a rise in temperature in tuberculous animals into which he injected a sterilised glycerine extract of pure cultures of tubercle bacilli, while it produced no effect whatever when the animals were free from that disease, furnished us with a simple but very reliable diagnostic agent. The effects produced by this discovery on the commercial aspect of the business of the dairyman and cattle-breeder have been in many instances most disastrous. Herds which were supposed to be free from disease were discovered by this test to be tuberculous; dairy businesses have been ruined—justly so we must admit, for no man has a right to sell milk or dairy products manufactured from them when derived from diseased cows any more than a breeder of pure-bred stock has to sell animals suffering from a contagious disease from which recovery is the exception. The exposure by this means of the prevalence of the disease, especially in dairy cattle, naturally aroused anxiety in the minds of the guardians of public health; a furore was thus created and the public mind was greatly disturbed when, in addition to this, its intercommunicability to human beings was made known. Hence we find many dairymen and cattlemen in all countries denouncing tuberculin and protesting against its use; not all dairymen, nor all breeders, however, joined in the denunciation of what is well known to be a safe, harmless, but reliable means of detecting this disease, even in its most incipient stages. In Canada during the past year, from Nov. 1st to Nov. 1st, there were 17,785 head of dairy cattle tested officially by voluntary application of the owners, on condition that the entire herd should be tested and all reacting animals quarantined for life, without compensation. Of this number only 358 reacted, or about 2 per cent. What opposition we met with came from breeders who had suspicious herds or herds which by private testing were known to be diseased; it came chiefly from men who combined importing for speculative purposes with breeding. In some of these cases the importers, we have reason to believe, were not ignorant of the cattle being tuberculous; in others we fear the man who paid the money was a victim of imposition or gross neglect of his interests on the part of his agent.

I will cite one instance of each case which came under my personal notice. (*a*) A herd of 13 cattle arrived at

Point Levis quarantine—two of them showing clinical symptoms of the disease, examination of the chart which accompanied them showed that it was not genuine It was therefore decided to test them, to which the person who had imported them objected, and while correspondence was going on one cow died from acute generalised tuberculosis, of the rest all reacted but one, and on post-mortem examination all were found to be tuberculous (*b*) A gentleman of large means decided to import a herd of useful but not high priced shorthorns He sent an agent to purchase and to import them This agent was instructed to use every precaution by testing and otherwise to secure animals free from tuberculosis They were bought in Ireland without being tested, they were brought to Scotland and there tested, two were rejected, the balance were shipped to Canada with a chart which was not quite satisfactory, and on testing them, by request of the owner, five out of 13 reacted

Personally I believe with Professor Nocard that tuberculin does not lie, how is it, then that so many tuberculous cattle come to us in America accompanied by charts and certificates of health? If the importer is a party to fraud, then he should be severely dealt with, if he is negligent, then he should pay the penalty of his negligence, for he has no right to import animals suffering from a contagious disease Is it p[illegible] in suspected cattle— [illegible] class of importer or [illegible] ional man employed to test for export imposed on by previous tuberculination nullifying or at least rendering uncertain his honestly applied test? Are all such men above suspicion? My own experience in a few instances in Canada compels me to say no Or is it the tuberculin that is at fault? When we meet with reactions varying from 40 to 90 per cent in cattle certified as healthy, as is found in both Canadian and United States importations, such questions force themselves on us and are sufficient explanation of why both Governments have each decided to keep a professional man in Britain on whose charts alone will cattle be allowed to pass through our quarantines without re testing

Reaction.—We are often asked by importers and testers in Britain what reaction we consider indicates tuberculosis Experience has taught us that it is not the extent of the rise in temperature so much as its character taken in conjunction with attendant circumstances Ordinarily a rise of 2° F above the highest normal is due to tubercle being present, but the single occurrence during the day of such a rise may be due to some accidental circumstance A typical reaction is arched, the maximum temperature occurring at the seventeenth hour, falling to normal about the twenty fourth hour or sooner in many cases The character of the reaction may be altered by copious draughts of cold water, or a lowering of the body temperature from any cause, so, also, does the raising of the body heat from such causes as flies, atmospheric heat, and scarcity of water, all of which produce variations in the reactions. In addition to which might be mentioned applying the test when the animal is excited from any cause, such as driving cows from the field to the stable, railroad journeys steamboat conveyance, change of climate, change of byre, bulling, stage of the disease (in advanced cases often no reaction follows) and, what to us is most important the uncertainty of reaction for months after injection of tuberculin. As I said above, tuberculin can be almost absolutely relied upon if properly used, there is no other diagnostic agent to be compared with it yet it is capable of much abuse, and is often improperly used

Objections urged against the tuberculin test—In my opinion there is not one tenable argument used by cattle owners or importers against its use I have never known a single instance of a person owning a healthy herd to lift up his voice against it, but I could multiply instances of men becoming almost maniacal in their denunciation of the test since it has been required in the international live-stock trade between the United States and Canada, as well as importations from Europe—men whose herds when tested reacted sufficiently to warrant one in suspecting previous knowledge from private testing on their part. With a view to get at the truth of some of their objections I sent a circular letter to inspectors throughout Canada, in which I asked replies to the following questions, suggested by newspaper discussions on the subject 1 "Do you know of any cases in which the use of tuberculin as a test has produced abortion? 2. Do you know of any instance in which a bull has been rendered impotent by the use of tuberculin? 3. Do you know of any case in which the general health of the animals has been injured by the tuberculin test? 4 How many cattle have you tested during the past year? 5. How many post mortem examinations have you witnessed of animals condemned in consequence of having reacted to the test? 6 In how many instances did you fail to find tubercle?" The replies are all negative to the first three questions, to the fourth they aggregate 22 023 head, to the fifth 579 and to the sixth 10, and one doubtful Professor Leonard Pearson, State Veterinarian for Pennsylvania, states, in his report for 1899, that "of 4400 post-mortem examinations made tuberculosis was found in all but eight animals that had reacted"

I also sent similar ques[illegible] had most experience wit[illegible] will represent the others "Do you think that the [illegible] says, 'No, I do not think there is the least injury in the tuberculin test Our herd of over 60 head have been tested three years in succession and I fail to notice any injurious effects whatever from the test' In answer to the second question 'Have you ever had any bad results that you could attribute to the use of tuberculin?' he says, "None I am using a bull that has been tested five years in succession and is seven years old and a more active, healthy animal I never saw—a very sure animal, you may judge, by our dairy of 42 cows, there is only one farrow As to abortion, we do not have near the trouble that we had before we commenced testing for I consider that we have a healthy herd now Previous to the testing of our dairy we had very serious trouble with abortion" (*b*) "1. I do not know of any case wherein the use of tuberculin has produced abortion, and on our farms we have tested cows at all stages up to within a very short time of calving 2 I have never known of a case wherein a bull was rendered impotent or injured in any degree whatever by the use of the tuberculin test 3 I have not known of a single case wherein the application of the tuberculin test affected prejudicially in the slightest degree the general health of animals tested therewith 4 We have had between 300 and 400 cattle tested 5 I have not personally witnessed any post-mortem examination, but I have had reports from the veterinary surgeon who does our work on every animal which was condemned as a result of the test and in almost every one positive traces of the disease were found."

From these facts we deduce the following —1 Tuberculosis is essentially a contagious disease and ought to be so classified and acknowledged by every country and state in the world as such 2. It is insidious in its character and in only a few cases comparatively can it be diagnosed by physical examination, but in tuberculin we have a safe and reliable test by which even latent cases can be diagnosed 3 That tuberculin is harmless It does not produce abortion in pregnant cows, impotency in bulls or in any way produce any injurious effects on animals tested by it

Methods adopted by different countries—Some years ago in Massachusetts compulsory testing was tried but was found to be impracticable and met with strong opposition. Belgium adopted somewhat similar methods with similar results It had to be given up and at present the killing is restricted to animals in which the diagnosis can be made by clinical examination In Switzerland free testing is practised. All clinically diseased animals are slaughtered, reacting animals are marked by cutting out a triangular portion of the ear In France there is immediate slaughter of clinically diseased animals and slaughter within one year of reacting ones In Germany tuberculin is furnished free and monetary aid is given to those who adopt the Danish system and otherwise resort to prophylactic measures for its eradication. In most of the German States it is required to sterilise the creamery and dairy products and their by products, skim and butter milk. In Denmark free testing is done on voluntary application Clinically diseased animals are killed, the others are divided into healthy and reacting These are separated in different buildings or partitions are used to divide the byres; in one section the healthy, in the other the diseased are placed. The reacting ones are bred from, the calves are reared on milk from healthy cows or pasteurised milk, or milk which has been heated sufficiently to kill the tubercle bacilli The success of this plan has been fully demonstrated by Professor Bang In America—both the United States and Canada—for a number of years all cattle imported from Europe were tested in the quarantines A few years ago importers urged that the practice too often led them into serious losses—the value of the diseased animals as well as freight and other expenses incurred—and discouraged, as a consequence, importation generally, and to meet the views of importers the Canadian Minister of Agriculture ordered that a number of veterinarians throughout Britain should be selected whose charts of test would be accepted without testing again in Canadian quarantines. This plan worked very badly, as numbers of diseased cattle were imported, several valuable herds being found clinically diseased, and were slaughtered. The United States had similar experiences with British charts of testing. This is regrettable, as both countries acknowledge the great results obtained by British breeders in producing excellent cattle, knowing as they do that on no spot on earth can cattle of equal merit be produced. There is something in the soil and the air of the sea-girt isle so favourable to the production of high-class bovines that breeders abroad must come to Britain for fresh blood to keep up their herds, otherwise marked degeneration is soon apparent. For this reason each country, rather than prohibit importation altogether, has appointed a veterinarian to do the testing, and on their charts alone cattle are admitted to both countries without being tested in quarantine. In Canada testing is done at Government expense, when voluntary application is made for testing the whole herd, and reacting animals are quarantined for life. Professor Bang's system is coming much into practice in Canada. In a few herds it has been successful in a remarkable degree. No compulsory measures have been tried. Tuberculosis exists in Canada to a limited extent only. No statistics for the entire Dominion are available, but the following figures indicate this. Testing has so far been confined almost entirely to dairy herds, and was employed in most of these owing to suspicion or knowledge of infection.

Year.	Tested.	Reacted.
1897-98	6,516	412
1898-99	16,882	451
1899-1900	17,785	358

The following regulations are enforced between the United States and Canada :—

Breeding stock.—Section 21 : All cattle to be admitted for breeding purposes shall be accompanied by : (*a*) a declaration made by the importer that they are actually for breeding and no other purposes ; (*b*) a certificate signed by a Government veterinarian specially selected and appointed for this duty, that they have been subjected to the tuberculin test and found free from tuberculosis. Such certificates must show the date of testing and chart of reaction with a description of the animal giving age and markings. The importer may be required to swear that the certificate refers to the animal represented. (*c*) A certificate of inspection signed by a Government veterinarian showing that the animals are free from contagious disease, and that no contagious disease of cattle (excepting tuberculosis and actinomycosis) exists in the district whence they came (*d*) When not accompanied by such certificates the animal or animals must be detained in quarantine for one week and subjected to the tuberculin test. (*e*) Should they be found tuberculous they must be returned to the country from which they were shipped or slaughtered without compensation.

Fat cattle and cattle for feeding, including range cattle for stocking ranches.—Section 22 : This class of animals shall be accompanied by a certificate of inspection signed by an official veterinarian showing that the animals are free from contagious disease and that no contagious disease of cattle (excepting tuberculosis and actinomycosis) exists in the district whence they came.

Settlers' cattle.—Section 23 : Settlers' cattle when accompanied by certificates of health to be admitted without detention ; when not so accompanied they must be inspected. Inspectors may subject any cattle showing symptoms of tuberculosis to the tuberculin test before allowing them to enter. Section 24 : Any cattle found tuberculous to be returned to the United States or killed without indemnity. The following extracts from copies of the laws and regulations governing the control and for the eradication of tuberculosis in individual States furnished to me by the authorities may be cited with advantage and can be found more in detail in a bulletin recently issued by Dr. Salmon, Chief of the Bureau of Animal Industry at Washington.

State legislation with reference to bovine tuberculosis.—Illinois.—Legislation under Board of Live Stock Commissioners. Their rules and regulations are as follows. All cases are reported to the Board. When physical condition indicates tuberculosis the animals are quarantined till tested under direction of the Board. A rise of two degrees or more (if in the opinion of the veterinarian in charge it is due to tuberculin) constitutes reaction and such animals must be isolated and held in quarantine till they are slaughtered and examined post mortem. A rise of 1·5°F. and less than two degrees is suspicious, and the animals must be isolated and quarantined for re-test. The maximum indemnity is not to exceed $75. The following is the classification for compensation. Class A.—No lesions: full appraisal. Class B.—Incipient disease: 75 per cent. of appraised value Class C.—Infected for one year: 50 per cent. of appraised value. Class D.—Infected for two years: 35 per cent. of appraised value. Class E.—Infected for three years: 25 per cent. of appraised value. Class F.—Infected more than three years: 15 per cent. of appraised value. Should the proceeds of the carcass exceed the percentage valuation, the owner receives the full amount. "Definite legislation needed with money to carry out provisions. Time not ripe for drastic measures."

Iowa.—No special legislation. Tuberculin is used where necessity and public safety demand. Reacting animals are tagged and quarantined, provision being made that they may be shipped to any abattoir in the State for slaughter, subject to inspection by bureau inspector, State veterinarian, or one of his assistants. No remuneration save what the animal will bring as a fertiliser. Thirty per cent. of the reacting animals are condemned on post-mortem examination. Work that is done is done thoroughly, but more is needed.

Kansas.—No specific law. Animals must be tested on entering the State, but may be brought in for show purposes without test, but if sold, they must be tested before they are allowed to stay in the State. At the present time there is litigation as to the legality of the rules and regulations.

Kentucky.—No special legislation. Animals may be dealt with by the State Board of Health. Animals cannot be condemned until examined by competent veterinarian. Indemnity is not provided.

Maine.—Commission of three persons appointed by the Governor. Necessary quarantine is enforced, half compensation being given for animals destroyed providing they have been in the State for a year or more. Compensation not to exceed $100 for pedigreed, or $50 for grade stock. Appraisal not being accepted by owner, rigid quarantine is enforced. The tuberculin test is not officially designated. The regulations are sufficient, but there are not enough funds for enforcing them properly.

Massachusetts.—General laws on contagious diseases cover tuberculosis. Compensation to the full value, not to exceed $40·00 in any case. Tuberculin is restricted to cattle brought in from without the State, excepting upon written request of the owner and on such animals as are condemned as being tuberculous by a competent veterinary surgeon. No compensation is granted unless the rules regarding disinfection, cleanliness, ventilation, light, and water-supply are complied with as directed by the commission. Owners using tuberculin are not entitled to indemnity for animals which react, unless the testing is done by the Board of Cattle Commissioners or by its direction. The regulations work well and good work is done, but more money could be spent to advantage.

Michigan.—General law on contagious diseases ; no special law on tuberculosis. The State veterinarian is acting under the general law against tuberculosis. On complaint of local board of health or individuals suspected cases of tuberculosis are tested. Reacting animals are destroyed or rigidly quarantined. There is no provision against entrance of tuberculous cattle The Governor has power to prevent, but the commissioner has not seen fit to protect the State.

Minnesota. — General legislation applies empowering local or State board of health to act Two tuberculin tests are required to condemn a tuberculous animal and must be given within three months and in not less than two months. There is no further legislation. Experience shows the inefficiency of procedure now in vogue.

Montana.—Towns of 5000 or over to have a meat and milk inspector who must be a graduate of a reputable veterinary medical college. All animals supplying milk to the public must have a certificate of tuberculin test and be inspected every month. The laws have just passed, and it is thought that they will prove sufficient if carried out to the letter. There is not much tuberculosis in the State—only about 5 per cent.

New Hampshire —General law relates to tuberculosis. Coöperation is general with the Federal bureau. The indemnity is the full appraised value, to be paid by the towns, which are reimbursed four-fifths by the State. Such animals must have been owned within the State three months before the detection of the disease. Cattle entering the State must be tested under the authority of the Board of Commissioners. Pasturage permits granted on physical examination by competent veterinarian—a graduate of a recognised school. Massachusetts cattle, tagged by the Massachusetts Cattle Commission, are allowed to go to New Hampshire for pasturing and to return to Massachusetts without test. Upon a request by cattle-owner he may have his herd officially inspected by the Board. If the inspector deems it necessary tuberculin is used, and the owner must conform to measures prescribed by the Board. The test applied is at the State's expense, and half value is given for all animals reacting. Precautionary measures to stamp out disease are at owner's expense. Experience shows that enforcement of sanitary measures is as important as the destruction of diseased animals. Ventilation, light, exercise of animals, and disinfection are regarded as the most important part of the work. Progress is being made in suppression and radical measures are not needed.

New Jersey.—Commission of seven, composed of the president and the secretary of the Board of Agriculture and five others appointed by the president, examine herds on request, but the tuberculin test is optional with the commission. Condemned [illegible] value and three-fourths are p[illegible]ithout the State are tested. [illegible]ing in prevalence by the education of farmers as to its character, and the need of greater care in breeding, stabling, sunlight, and ventilation.

State of New York.—Tuberculin applied upon written request under conditions prescribed by the Commissioner of Agriculture. The commissioner may order the test, holding a reacting animal in strict quarantine. He may condemn, quarantine, or slaughter when tuberculosis is found on physical examination. Compensation shall not exceed $60.00 [illegible] or other dangerously contagious or infectious disease no compensation is allowed. Animals entering the State which pass the Federal authorities are allowed to proceed.

[illegible] or be examined by State official. Tuberculin test is not specified.

Pennsylvania.—All animals entering the State must be tested with tuberculin. Other testing is left to the discretion of the Board. Compensation is not more than $25 00 for infected grade and $50.00 for infected registered stock. Measures for combating this disease as well as others are at the discretion of the Board and are not flexible.

Rhode Island.—Appraisal for "scrub" animal $50 00, grade $75 00, and registered $100.00. In event of an animal being found infected at necropsy the State pays half the value, but if healthy the full value. The animal must be owned within the State at least three months previously. Cattle coming into the State must be tested with tuberculin

Utah.—Cattle having tuberculosis shall not be kept by dairymen and shall be killed by the Dairy and Food Commissioners. There is no provision for the tuberculin test or for indemnity.

Vermont.—Tuberculin test is applied without expense on application and the whole herd must be tested. Such herds cannot admit new animals unless they undergo the test. Reacting animals must be killed and buried or burned at the expense of the owners, who retain the hides. The Board regulates a right to re-test when considered necessary. The rules of the Board where herds are tested regarding disinfection must be observed. Cattle entering the State from without must be tested by a person approved by the Board and the expense is borne by the owner. Animals killed by written order of the Board are appraised, such appraisal not to exceed $40.00. A necropsy is held, and if tuberculosis or other disease dangerous to public health is f[illegible] are followed the disease is stamped out. Persuasion is used by the Board to induce testing of the suspected herd. These measures are radical enough at present, for the public must be considered and be in sympathy with the movement rather than antagonistic.

Virginia.—Tuberculosis is classed as a highly contagious and infectious disease. The Board of Control of Agricultural College has power to enforce such measures for its control as are deemed necessary.

Educate the People.—Educate the people by furnishing them with the most important scientific and practical facts which are known about the disease. Much good has been done in Canada by the distribution broadcast of bulletins from which the following items are extracted:—

Tuberculosis.—This disease claims for its victims nearly, perhaps we might say, all the domestic animals, and few of the wild animals subjected to domestication resist the contagion, as is well known to keepers of menageries. Rats, mice, and other vermin which inhabit houses and outbuildings not only contract the disease but are active agents in spreading it. Some species are more susceptible than others, and contract it readily by eating food containing the germ of the disease, or by inhaling the dried germs given off from the lungs, throat, uterus, or intestines of animals affected in these organs. The most susceptible of the domestic animals are cattle, swine, chickens, goats, and rabbits. These contract it readily in the natural way, but it can be produced in sheep, dogs, cats, and horses by inoculation with tuberculous material. Tuberculosis in the lower animals is the analogue of consumption in the human family. It is due to a similar germ (bacillus tuberculosis bovis); it is, however, more virulent than the human bacillus. It is communicable from other animals to man, and from man to the lower animals, by natural infection and inoculation.

Tubercle.—The germs (bacilli), which are living organisms of minute microscopic size, when they reach and become located in a tissue, produce local irritation and the formation of small reddened areas infiltrated with fluid and cells. These are the tubercles. As they become older they enlarge, and their colour is greyish or yellow from changes that take place within, causing the death of the central tissues. Their appearance and consistence in this way resemble that of cheese. These nodules may vary in size from a pinhead to a cocoanut, often they are of stony hardness from the presence of lime salts. The tubercles, for example, may be confined to one organ or tissue of the body, such as the lymphatic glands of the mesentery or thorax, or the throat, udder, ovaries, &c., or they may be generalised throughout the body, the germs travelling in the blood circulation. In this way the abdominal organs (the liver, spleen, kidneys, &c.) may all be involved as well as those of the thorax, lungs, pleura, lymph glands, &c. Often the pleura and peritoneum are covered with grape-like excrescences the appearances of [illegible] this disease. Wherever tubercles [illegible] time much destruction occurs in [illegible]

The tubercle bacillus.—This is described as a rod-shaped organism with rounded ends and a slight curve, requiring complex laboratory methods of cultivation and staining to [illegible] for microscopic study. It is a parasitic organism [illegible] excretions of animals [illegible] badly in the sunlight, which is said to kill it in from a few minutes to several hours. This fact should be remembered in dealing with it with a view to preventing tuberculosis. The invasion of the animal's body by the entrance into it of living bacilli is effected either through the digestive organs (ingestion) or by the respiratory organs (inhalation), by transmission to the sexual organs when the testicle is invaded and by inoculation, or by a cut or abraded surface. Without the entrance of the living bacillus into the body tuberculosis cannot affect it. It is the seed from which it grows, and it is as essential to the development of the disease as oats, peas, or potatoes are to reproduce these plants.

What renders cattle susceptible to this disease?—Impaired health, from whatever cause it arises, renders cattle susceptible [illegible] Heredity has been proved not to be an [illegible] It is well established by the [illegible] and others that calves may be bred from tuberculous mothers, and if removed before the cow licks them or they have sucked their mother's milk, placed in absolutely healthy surroundings and fed on milk from healthy cows, they can be reared and remain, so far as any inherited disease is concerned, perfectly free. In-and-in breeding by producing animals with reduced vitality, over-milking, under-feeding, want of sunlight, pure air, or sufficient exercise, breeding too young, are all what may be termed predisposing causes to tuberculosis and should be avoided. One breed of cattle is just as liable to contract this disease as another when subjected to the predisposing and exciting causes. Dairy cattle are most subject to it because they are more exposed—they are more congregated, more closely and continuously housed, their vitality is more drained by heavy milking, and they are kept longer than the beef breeds. Their calves are more liable to milk infection, as they are fed on mixed milk, whereas the beef breeds usually suckle their calves. The majority of beef cattle are killed off at three or four years old, hence they are exposed to the contagion for a shorter term of life, which is spent more in the open air and in sunlight.

How the disease is usually introduced into a herd and how it extends in it.—A tuberculous bull is probably the most active agent in spreading this disease, both by cohabitation and by sexual connexion. Farmers cannot be over-cautious in buying a bull or in having cows served by one till he has been subjected to the tuberculin test and found free from the disease. Nothing should induce a breeder to allow contact with his healthy cattle by a bull till he has every assurance that he is free from tuberculosis. Tuberculous animals of any kind should be prevented from coming in contact with the cattle.

Tuberculous attendants.—Tuberculous attendants—men or women suffering from pulmonary consumption—should on no account be allowed to feed, milk, or have anything to do with cattle or pigs. The intercommunicability of the disease from animals to man, and from man to animals, is an established fact and is no longer open to discussion. The bacilli from the throat and lungs of diseased people or animals, being coughed up, adhere to and dry on the woodwork, walls, floors, and feed-boxes in buildings, cattle-trucks, or stockyards, and the dust being moved about by air-currents, being inhaled, infects the respiratory organs, gains access to the blood-stream or lymphatic glands, or mixing with the food in the hay-rack or feed-trough, finds access to the stomach and intestines, and thence through the blood or lymph channels to the abdominal glands and other organs.

Danger from milk.—The virulence of milk from tuberculous cattle, especially when the udder is diseased, has been clearly demonstrated. It will communicate the disease even when the milk is diluted by mixing with large quantities of other milk in the creamery or cheese factory; whey is equally dangerous. Milk from cows in advanced stages of generalised tuberculosis is also dangerous, but milk from cows in early stages of localised tuberculosis may not prove infective to calves or persons fed on it. It should, however, be sterilised by heat before being used. The germs remain active in skim-milk and whey and may produce the disease in calves fed on it. Milk obtained from creameries in districts where tuberculosis prevails should be raised in temperature for 10 minutes to 180° F. before being given to calves, otherwise living bacilli may be taken into the stomach, and, entering the lymph channels, produce the disease. As a precautionary measure, milk from tuberculous cows should not be received at creameries or cheese factories. Unless this is done creameries and cheese factories may become distributing agents of the disease to healthy herds. Milk from tuberculous cows is a frequent source of communication of the disease from cattle to people, especially children and old, feeble persons.

How to prevent its introduction to a herd.—See that your animals to begin with are free from the disease. Never bring any animal into the byre till you have ascertained beyond a doubt that it is healthy. Keep your own bull. Your neighbour may be obliging, but if he is careless about the health of his stock you may suffer irreparable injury by accepting even the free use of his bull should the animal happen to be tuberculous. Conversely, if you have a bull, be exceedingly careful to see that no tuberculous cows are brought to him for service. Never allow a consumptive person to have anything to do with your cattle; make no mistake about this. Your byres must be well lighted—almost as light as outdoors; disease germs are killed by sunlight. Pure air and plenty of it is essential to health. This can only be provided by sufficient space. Let your cow stable be roomy. Drainage is essential to the purity of the air. Without proper and efficient drainage the air must become contaminated by the emanations from the droppings and urine of the cattle as well as by the decomposing vegetable matters with which they are mixed. Drain your buildings, and do it thoroughly. The ventilation is all-important. By properly arranged ventilators the impure air is removed and replaced by pure air. The oxygen of the air is constantly being consumed in the process of breathing and unless it is replaced it becomes unfit to sustain animal life. The constant change of the air in buildings inhabited by animals is absolutely necessary to preserve health. During summer weather most buildings are sufficiently ventilated by the doors and windows being left open; it is during the winter, when cattle are housed, that they suffer from imperfect ventilation Proper ventilation provides for the admission of the pure and the escape of the foul air. As a rule, farmers' architects do not make sufficient provision for either. The air may be admitted by openings near the floor and by windows hinged at the bottom and dropping inward. The ventilators or air-shafts are usually too small. Most buildings require shafts three feet square, placed about 20 feet apart, in the middle aisle of the byre. The shafts should be divided inside into two by a partition extending from the top to within three feet of the ceiling, the opening being controlled by trap-doors opened or closed by cords running through pulleys.

Cattle standing head-to-head objectionable.—The common plan of arranging the byre, so as to save labour in feeding, by having an alleyway with the heads of the cattle opposite each other, is objectionable from a health standpoint, as it exposes animals opposite to tuberculous cattle much more to the contagion than when they are placed with their heads to the wall. They may be easier fed the former way, but they are easier cleaned the latter, and it has a decided sanitary advantage should contagious disease exist. Running water in troughs placed in front of the cattle is objectionable if tuberculosis is present, as by this means the germs may be carried to the whole herd.

Symptoms and diagnosis of tuberculosis.—In the majority of cases the symptoms are obscure, and till the discovery by Professor Koch of the reaction produced by the injection of tuberculin (being a most reliable test for discovering this disease in obscure cases unrecognisable by symptoms), the majority of cases could not be detected even by experts. When affecting the lungs, throat, and respiratory organs generally it is accompanied by a frequent cough but no fever. There is disturbance of respiration; the breathing is quickened by slight exertion or excitement, and the cough is produced by changes of temperature. The expert can detect dull spots surrounded by areas of increased resonance on examination of the lungs by the usual methods. Usually the superficial glands in the throat, between the jaws, or under the ear or the udder may be hard and swollen. The animals may continue for months or even years to maintain fair condition; they are sometimes fat while the lungs may be found studded by large tuberculous masses. When the disease is abdominal and the glands and organs in the belly are chiefly affected, the symptoms of defective nutrition are early apparent—emaciation, lessened secretion of milk, indigestion, breathlessness, and general failure more or less rapid. Many cases cannot be detected by symptoms, but can be revealed almost to a certainty by the tuberculin test.

The tuberculin test.—Until the discovery by Professor Koch in his experiments to find a cure for consumption in human beings that the injection of tuberculin invariably caused a rise in temperature when the person or animal was tuberculous, while it produced no effect whatever when free from it, the detection of the disease in early stages or when slightly affected was considered impossible in most cases. This test is most delicate and reliable (about 98 per cent.) where it is properly applied. Tuberculin is a soluble product of cultures of tubercle bacilli, of which a glycerine extract is made, which is sterilised by heat and filtered through porcelain, so that it contains no living germs and therefore cannot produce tuberculosis in animals injected with it. It has therefore no effect on healthy animals; in some cases the disease is aggravated by it when it exists, but it cannot be produced by it.[2] The lymph must not be exposed to sunlight, it must not be frozen, and it must be kept well corked to exclude air. Tuberculin injection has no bad effects on the secretion of milk. The consensus of opinion of those most experienced is that it does not lessen the secretion of milk in dairy cattle, consequently these may be tested even when they are in full milk without disturbing its secretion unless it be during the few hours of its absorption. It has never been known to cause abortion in cows or sterility in bulls, as has been claimed by its opponents; in fact some breeders state that it lessens abortion. The consensus of unprejudiced opinion is that it is harmless to cattle, even when tubercle is present, and in some cases it exercises curative influence. Dose.—The dose varies with the size and age. As issued by the Department of Agriculture it is ready for use, with doses marked on the bottle—viz., 20 drops for calves, 40 drops for small or medium sized animals, 60 drops for larger, and 80 drops for very large ones When second tests are considered necessary at least 90 days should elapse and the doses should be slightly increased. Second tests are quite unreliable and often deceptive.

---

[2] It would be as reasonable to expect barley to grow from whisky placed in the ground as tubercle from injecting tuberculin into an animal body.

How to deal with a diseased herd —When tuberculosis is discovered in a herd immediately remove the diseased animals from the healthy to an isolated stable, or a part of the byre may be partitioned off by close boards as far as possible from the rest of the herd In the case of low-priced cattle the owner will best serve his own interests by slaughtering them at once When they are especially valuable and in calf, the experiments of Professor Bang and others show that the calf may be saved by removing it as soon as born and before the cow has licked it or it has been suckled by its diseased mother, and by placing it in an uninfected building and feeding it on milk from tested cows, it will in all probability grow up free from tuberculosis The herd should be tested every six months and those animals which react should likewise be removed till all symptoms have disappeared

Disinfection of premises —Most careful and complete disinfection of buildings and yards in which diseased cattle have been kept should be employed to rid them of disease germs In doing this, before sweeping, sprinkle the floors and walls thoroughly with water to prevent dust rising, removing drinking-troughs, feed-boxes, and stall divisions The floors must be specially scrubbed, the walls, ceilings, and partitions should be carefully washed, and all freely sprayed with a disinfectant solution such as carbolic acid (one pint of crude acid to four gallons of water) or lime-wash. It may be applied by a whitewash brush or by a spraying pump, care being taken to see that every corner, crack, and joint is thoroughly penetrated by it The cleansing and disinfection should extend to drinking troughs and fences of the barnyard to make disinfection complete

Disposal of tuberculous carcasses —Should the disease be local as is frequently the case, being confined to one or more glands, the flesh can be used as food with impunity Infection from flesh is an extremely rare occurrence, and most unlikely to occur if it has been thoroughly cooked. This can be most relied on when it is cooked in the minced form, deep seated portions of large roasts may not be exposed to sufficient heat to kill the bacilli When on post-mortem examination the disease is found to be generalised the carcass should be put into the vat, the diseased viscera and tuberculous masses should be burned or buried deeply in lime No restriction is necessary on the sale and removal of hides, horns, hoofs, or hair

Insurance —At the Seventh International Veterinary Congress, held at Baden Baden two years ago, Professor Siedamgrotzky suggested a system of insurance which, if it could be carried out, would be a common sense way of lessening individual losses consequent on eradication by slaughter of clinically diseased and reacting animals This is surrounded by many practical difficulties, yet it is well worthy of the consideration of this Congress An effort should be made to provide an indemnity fund by this or some other way, the public purse contributing a liberal share, otherwise, I fear that the progress made in eradication will be slow In the State of Illinois, United States of America, indemnity is paid by the State on a plan which is worthy of imitation A maximum value is fixed at, say, £15 Diseased cattle are classified as follows after being slaughtered —

	Indemnity
Class A, in which no lesions are found.	Full appraised value
" B, in incipient stage	75 per cent appraised value
" C, infected for one year	50 " " "
" D " " two years ...	35 " " "
" E " " three " .	25 " " "
" F " " over three years	15 " " "

Should the proceeds of the sale of the carcass exceed the percentage valuation the owner is paid the full amount so received

Suggested legislation —No legislation will accomplish the end in view unless the measures are such that the public are in sympathy with them rather than antagonistic to them

I Tuberculosis should be included in the list of contagious diseases. Tuberculous animals should consequently come under the provisions of the Animal Contagious Diseases Act; but the local *authorities* should have power to allow the sale and movement of such parts of the *carcasses* as are known not to carry *contagion*, such as hides, *hoofs*, horns, and hair, thus preventing *unnecessary loss*

II All foreign animals admitted *for breeding* or dairy purposes should be tested by the tuberculin test. Tuberculous animals should be prohibited from entering

III Tuberculin should be controlled, and none but qualified veterinarians should be allowed *to* use *it, and all* reacting animals should be reported, marked, and quarantined

IV All animals showing clinical symptoms of tuberculosis, especially disease of the udder, lungs, uterus, or bowels, should be killed at once, and all scrub and grade animals reacting should be killed within six *months* Pure-bred cattle may be bred from under Professor Bang's system, in quarantine for life

V All testing, other than imported animals, should be by voluntary application for a test of the entire herd, and the expense should be borne by the State A reaction of 2° to be understood to indicate tuberculosis, 1½° as suspicious Suspicious animals to be quarantined and re tested in three months, unless clinical symptoms develop, when they should be at once condemned The Government to have the right to order a re test when considered necessary

VI Disinfection of premises should be ordered by special regulations, the carrying out of which should be superintended by Government officials

TUBERCULOSIS AMONG AUSTRALIAN STOCK[1]

BY G PENTLAND,

CHIEF INSPECTOR OF STOCK FOR THE STATE OF VICTORIA

EARLY in the year 1883 the attention of the district and border staff was called by the late chief inspector of stock, Mr Curr, to the fact that diseases of cattle known as tuberculosis (consumption) and ' cancer" (lumpy jaw), now known as "actinomycosis,' were becoming more common and appeared to be gaining ground At that time little was known of the nature of these diseases, but the brilliant discovery by Professor Koch in 1882 of the cause of tuberculosis being a minute rod like organism, the bacillus tuberculosis, awoke the scientists *of the world to inquire into the* value of this great discovery In 1883 the Hon James Buchanan, M L.C, an experienced stock owner, called the attention of the Victorian Government to the fact that it was necessary that a board of experts should be appointed "to inquire into the existence and extent in this colony of the disease in cattle known as tuberculosis, whether its existence is likely to be detrimental to the public health, and what preventive measures should be adopted", and in 1885 the board recommended after very exhaustive inquiries that tuberculosis be placed on *the schedule of contagious diseases* under the Stock Act 1870 This was done in the year 1887, and since then this department has been able to deal with visibly affected animals in the same way as pleuro pneumonia and other infectious diseases Previously to this power being given by law there was no power to cause tuberculous animals to be destroyed, although a large number were willingly destroyed by owners at the instance of inspectors, who, to a large extent used moral suasion in these matters We are now constantly destroying affected animals in the course of our inspections, both *in the districts and* on the borders, as the annual returns hereunder show In the year 1893 special instructions were given by the Secretary for Agriculture to have all dairy cattle inspected as closely as possible by the district staff, and I think I am safe in saying that this instruction has been faithfully carried out The district staff is composed of practical men experienced amongst stock and accustomed to country life and the ways of the bush They have in the past been successful in stamping out scab, and have also met with great success in coping with and keeping down pleuro-pneumonia by the measures of slaughter, quarantine and inoculation.

---

[1] A paper communicated to the British Congress on Tuberculosis, Section IV, Veterinary

The duty of combating tuberculosis has fallen to the stock branch whose primary business is to see that infectious and contagious diseases are kept out by land and sea and to prevent the spread of any infectious or contagious disease within the State. Tuberculosis, pleuro-pneumonia, and actinomycosis are all imported diseases; they were introduced at a time when there was no department for their prevention or control, and hence they gained great headway in consequence and would do so again if there were no stock departments throughout Australasia to keep them in check. Besides having practical and experienced men to travel the districts, there are attached to the department six veterinary surgeons in private practice whose services are sought in special cases where special inquiry or demonstration is necessary. They are called upon, in conjunction with inspectors of stock, to inspect before landing all foreign stock arriving at port, and then again before release from quarantine. We thus have a staff equal to any emergency, and in the regulations we have hard-and-fast rules for the guidance of owners of stock and the general staff.

As regards the general condition of dairy stock, I reported in June, 1893, that dairymen as a rule vie with each other in keeping the best class of stock, it being the best cows that yield a profit, and that odd cases of tuberculosis crop up once in a way which they readily get rid of; but that on the whole the health of our dairy stock was excellent and would compare favourably with the same class in any part of the world. Owners are only too anxious to maintain the excellence that has been obtained. In a report dated Nov. 2nd, 1896, I stated that it was upon the principle of stock-owners, aided by the inspectorial staff, destroying diseased animals themselves that pleuro-pneumonia was kept in check, and it has been upon the same principle and with the same aid that tuberculosis has been got under. The greatest factor, however, we have in preventing the spread of tuberculosis is the open-air life which our cattle live, and this fact accounts for their greater freedom from tuberculous disease than the cattle of Great Britain, Denmark, and other European countries, which are housed and hand-fed for the best part of the year. On disease breaking out in the confined atmospheres of byres the infection spreads rapidly throughout, and there is a larger percentage of animals affected than there would be if they were living under more favourable conditions of hygiene. We therefore have an advantage over countries the climatic conditions of which are not so favourable as ours. The sun's rays, too, are all-powerful in destroying the bacillus of tuberculosis, and the success of any scheme for getting rid of and keeping rid of tuberculosis will depend upon cleanliness and upon having cowsheds and yards built so as to get as much sunlight as possible. It is to be remembered that darkness, dirt, overcrowding, and imperfect ventilation favour the spread of tuberculosis. No infected or suspected animals should be allowed to mix with healthy animals. Among the many ways of spreading infection is that of healthy animals licking affected ones; and in small dusty areas or yards where diseased animals have been the dry particles containing the germs of disease are floating about and are therefore a menace to man and beast.

Since 1885, the year of the board's report, which showed that 7 per cent. of all cattle were affected in various degrees, the percentage has been decreasing at a satisfactory rate according to the statistics obtained at the city abattoirs. In 1896 the return showed that all cattle were affected to the extent of 4 per cent., and a later return for 12 months ending June 30th, 1899, showed that bullocks were affected to the extent of 3 per cent., cows 5 per cent., and calves to the extent of one only out of 3935. For the year ending Dec. 31st, 1900, the return furnished by the superintendent of city abattoirs is as follows :—

Cattle.	Tuberculosis.		
	Number slaughtered and inspected.	Number affected in various degrees.	Number condemned and destroyed.
Bullocks	36,125	No record kept.	66
Cows	8,517		64
Calves	3,532		*Nil.*
Totals ..	43,174	—	130

The percentage of disease found at the city abattoirs is necessarily much greater than that found by inspectors in live stock, and therefore it is only the rough of the herds that is culled, so that affected animals showing no external signs escape; but, nevertheless, the general condition of our dairy and other classes of cattle is improved, whilst in every animal that is destroyed and the carcass burnt the centres of contagion are thereby lessened and kept in check and suspicious cases are dealt with under the tuberculin test or by isolation. The following statement shows the number of dairy and other cattle inspected and killed in the districts on account of tuberculosis for the period 1894–1900 :—

Year.	Cattle.	Number inspected.	Killed for tuberculosis.
1894	Dairy	119,450	315
	Other	194,373	276
1895	Dairy	108,169	325
	Other	236,651	269
1896	Dairy	120,709	320
	Other	245,448	229
1897	Dairy	102,972	270
	Other	227,167	182
1898	Dairy	91,397	220
	Other	257,387	237
1899	Dairy	87,360	151
	Other	227,008	141
1900	Dairy	85,413	115
	Other	202,044	114
Total killed ...	—	—	3164

Owners of tuberculous stock are generally only too pleased to get rid of diseased stock without delay and without compensation, their motto being, "The first loss is always the best loss." No compensation was given in the cases of scab or of pleuro-pneumonia. It was only given when an outbreak of a new disease—foot-and-mouth disease—occurred in this colony about 30 years ago and in the case of some scabby sheep being illegally destroyed. Compensation for valueless beasts has not been asked for by owners of cattle or sheep, as they do not place any value on stock suffering from disease, and they readily consent to destruction without raising the question of compensation when inspectors make their condemnation. Clause 10 of the Act clinches this matter, as it provides that under an Order in Council owners of diseased stock shall have no claim for compensation when destroyed at the instance of inspectors. Diseased animals are usually destroyed and opened on the nearest available spot and the diseased parts are shown to the owner who profits by the object-lesson. This course is highly educational to them in getting affected beasts destroyed at once, without waiting for the action of the department. In the case of the tuberculin test I may state that owners of apparently healthy animals reacting and slaughtered, and showing but slight lesions, complain of the losses they sustain, and would claim compensation in such cases if the tuberculin test were compulsory. Some owners argue that their cattle might live for years where the lesions are slight and might heal up or make no further progress; but, on the other hand, if the test disclosed generalised tuberculosis, or one or more organs were badly affected, then they would not apply to be compensated.

The Diseases in Stock Act, 1890, consolidating the laws relating to diseases in stock, provides by Section 6 that inspectors of stock shall have power to enter at any time into any ship or any land, or into any building, not being a dwelling-house, for the purpose of inspecting any stock. This is a power which enables an inspector to find out for himself the state of his district as regards disease, and has a certain amount of influence among stock-owners in reporting disease. I understand that in England inspectors have no such power, and if this be the case owners of affected stock can do just as they like—they may either report disease or give notice of such for compensation or may send stock that has been in contact with affected stock to the market yards for sale, since they have nothing to fear whilst an inspector has no power of entering. Regulations for placing diseased stock in quarantine are in force in this State and this power judiciously exercised enables an inspector to have affected stock destroyed at once, with the consent of the owner. The owner readily consents to destroy

has in seizing
other stock in
to destroy his
tained and in
this he has the right to appear As regards foreign and inter State stock we have sufficient power to fix any condition that may be justifiable for introducing certain kinds of stock, and this enables us to prevent animals being introduced by sea or land if they are affected with tuberculosis or any other disease, and the Health Act gives power to prohibit the entry of any kind of stock whether diseased or not Members of the police force generally assist the district inspectors The districts, however, assigned to each inspector for the inspection of dairy cattle are too large and unwieldy and the requirements of the dairying industry, which has grown so large of late years, justify closer and more regular inspection than obtains at the present time

Unlike other infectious and contagious diseases tuberculosis is so slow of development that it is impossible to say how many animals in a herd are affected. It was hoped, when the tuberculin test was discovered, that results of a satisfactory nature would be afforded to the cattle raising industry, but so far there does not seem to be any great desire on the part of Australian cattle-owners to have the test applied to their herds The cattle that react should be "dried off" and fattened for slaughter, whatever the result may be when opened The test considered from the most favourable point of view,
that to make it a Gc
the destruction of
would certainly require to be provided and in this matter it has been estimated that in England it would take £19 000 000 sterling to get rid of the disease Three and a quarter millions of cows would have to be taken from the milking sheds and slaughtered. This is a very grave matter and points to the necessity of other alternatives or ameliorative measures being devised I know of no better method of gradually getting rid of tuberculosis than plenty of fresh air, sunshine, and slaughter of visibly affected beasts The sun s rays are death to the bacillus of this disease, therefore every effort should be made by the people in the old country to try hygienic methods for the cure of tuberculosis both in man and beast This fact is sufficient for the local authorities to have sanitary laws enforced the doing away with everything that tends to promote disease *the thorough ventilation and drainage of byres, and the* cleaning and keeping clean of all cows in milk and the utensils nd gearing used in connexion with the dairy These matters cannot be repeated too often for it stands to reason that the more fresh air we get the more vitality we have of resisting the enemy A stock owner has a perfect right to get rid of disease in his dairy herd in the same way as Her late Majesty the Queen did in getting rid of the cows which reacted to the tuberculin test at Windsor This is a matter which touches the pockets of owners directly, and no one can take exception to any owner attempting to purify his herd in the most effective manner he can.

The United States have not been slow in following up the discovery of Professor Koch s tuberculin cure for consumption in the human being The State of Vermont some years ago made experiments in regard to the te t One of the objections taken to it was that tuberculin does not determine the stage of the disease but condemns animals that might live for years and possibly recover This objection seems to me a fatal one in respect to making the test a compulsory measure, and therefore it can only be a means of privately finding out whether tuberculosis exists or not It appears, therefore that we have yet to hear of other scientific methods of a more exact nature than that disclosed by the tuberculin test The test does not allay the progress of the disease, but on the contrary increases its severity stirs the minutest lesions, and therefore brings to a climax the disease in a generalised form dormant for all time to
come methods as the easiest
and berculosis and if the
tuberculin test is not allowed in the case of the human being, why should its use be advocated in the case of the bovine species? Some of the cattle breeders of the United States and Canada have protested against the use of tuberculin as a test for pure bred cattle being allowed to be imported, on the ground that it is "unreliable and unsatisfactory," and in the same sentence it is pointed out that it is of great use to the cattle-owner who wishes to maintain a healthy herd, but that importe l stud cattle should not be subjected to the test As regards this exception I can only say that importers of pure bred cattle in the State of Victoria have it in their power to have their cattle tested if they please before shipping them from foreign ports and this has been done in one or two instances within the last two years The quarantine of all suspected animals should be insisted on which react to tuberculin with the alternative of immediate slaughter if quarantine cannot be maintained. I have lately heard of a stock owner having gone to the trouble of getting his herd subjected professionally to the tuberculin test and then when the animals which were put away to fatten had been killed the tuberculin test proved to be satisfactory Cases of this kind I should be glad to have made official or at any rate brought under official observation

---

ON THE MORTALITY AMONG RATS AT THE CAPE TOWN DOCKS WHICH PRECEDED THE PRESENT EPIDEMIC OF PLAGUE

BY ALEXANDER EDINGTON, M D , F R S EDIN ,
DIRECTOR OF THE BACTERIOLOGICAL INSTITUTE CAPE COLONY

IN the report of the meeting of the Epidemiological Society on May 17th as published in THE LANCET of June 1st, p 1541, certain remarks are contained with reference to a mortality among rats in the Cape Town Docks and Dr Klein is reported as having said "Dr Edington now admitted the mortality among rats at Cape Town and had sent cultures obtained from them to several bacteriologists, including himself There was no doubt as to their being true plague bacilli Dr Edington s failure to recognise them having been due to his employing unsuitable media ' Since this statement is totally inadequate and, as a matter of fact, really mis states the case I have thought it advisable in the following brief account to recount the facts of the case

I arrived at Cape Town *en route* to my headquarters at Grahamstown on Feb 5th At Cape Town, however, I was *detained* by the Honourable the Colonial Secretary in order to investigate an alleged mortality among rats at the docks Accounts from reliable per ons went to show that rats had been dying at the docks in some appreciable numbers but in an official letter of Feb 9th the Table Bay Harbour Board stated in regard to the alleged mortality that it had been ' brought to the notice of the board s officials and it was attributed to the energies of the rat-catcher which had been newly awakened by the threatened appointment of another man ' I found in so far as my information went, that rats had been dying in appreciable numbers for two months previous to my arrival Professor Simpson, in a recent address given to the Cape Town branch of the British Medical Association states that "the sickness and mortality among rats prevailed for at least four months before the fir t recognised case of plague This is a long time to elap e without any manifestation of the disease in man

Immediately that I had been asked to make an investigation the Under Colonial Secretary, at my request, issued instructions that rats found dead or dying at the docks should be immediately sent to me Despite every effort however during the following six days no rats were found and I was *forced to report at that time that so far no* evidence had been brought before me which could enable me to say that rats were dying from plague On the following day, however a rat was brought to me from the south arm of the dock (the area in which the mortality had actually been observed formerly) and a number of rats from other parts Of tho e brought from other parts not one was found which showed the slightest evidence of disease I ought to say here that with two exceptions all of them were alive and in perfect health while of the two which were dead no evidence of disease was found at all That one however from the south arm showed conditions which are of very great interest and I shall refer to it in detail Meanwhile having heard on Feb 10th that several suspicious cases of sickness in man, together with one which I had just seen, had been removed to the isolation camp at Uitvlugt, and having received authority on Feb. 11th to examine these, I proceeded there on the morning of Feb. 12th. On my arrival I found that 12 patients had been admitted, most of whom had well-marked buboes, either in the femoral or axillary regions. I opened into most of these buboes with a sterilised hypodermic syringe and in the material thus collected I was able in most instances to demonstrate the presence of the plague bacilli. Thereupon I reported officially to the Colonial Secretary on Feb. 13th "that the disease now appearing in Cape Town is undoubtedly the bubonic plague."

Cultivation experiments were also successfully carried out, and since that date I have produced the disease by inoculation of the cultures in guinea-pigs and rabbits. I was detained at Cape Town for only a fortnight, and as when I arrived there originally I had no materials for culture experiments I telegraphed to Grahamstown for them and they arrived four days later. All the culture material (agar-agar) came from one batch and upon it the human plague bacilli reproduced themselves in characteristic microscopic form and have retained their virulence in successive transferences until now when it (the original strain, not passed through an animal) is now showing a very definite declension in virulence. I have referred to this thus fully as controverting the statement that I had used unsuitable media, since the bacilli of the rat plague, grown on the same media and inoculated simultaneously with the human plague, produced bacteria of the most diverse character.

But to return to the case of the rat from the south arm. It was examined with the assistance of the principal veterinary surgeon, Mr. Duncan Hutcheon, M.R.C.V.S., and a very complete dissection was made. On removing the skin no injection of the subcutaneous tissue was observable, nor were any enlarged glands found either in the axillary, femoral regions, nor, afterwards, in the abdomen. On opening into the abdomen no peritoneal exudation was seen, while the intestines were quite normal. The adrenals were pale and slightly enlarged, but the kidneys were normal. The spleen, which consisted of a mere ribbon, was certainly not enlarged, while its consistence was normal. The liver was slightly congested. No enlarged glands were found. On opening into the pleural cavity we found a large collection of clear yellow exudation. The lungs otherwise appeared absolutely healthy. The pericardium was also filled with clear yellow exudation to such an extent as to make the membrane tense. No hæmorrhagic exudations were found in connexion with the heart-muscle or the endocardium. Thus far the post-mortem examination had failed to reveal any suggestion of plague infection. Cultivation experiments were instituted with the spleen-pulp and the blood of the heart, the results of which I shall refer to later. Microscopical examination was made of the blood from the axilla and also from the heart, whilst smears were made from the liver, spleen, adrenals, and kidneys. In all of these, and especially the spleen, large numbers of a somewhat ovoid bacterium were found. These were very regular in size and shape and did not show bipolar staining either with Löffler's blue or gentian violet. They were thus in marked contrast with the bacilli found in the human buboes, in which typical bipolar staining was found in every case. I therefore reported in regard to my examination of the various organs, blood, &c., that "in all of these, but least of all the suprarenal capsules, there are numbers, often innumerable, of a microbe which is somewhat similar to one stage of the plague bacilli, with which, however, it differs in many respects."

As I was under instructions, dated Feb. 16th, having already declared the disease at Cape Town to be bubonic plague, to proceed to Grahamstown and to re-assume the charge of the Bacteriological Institute no inoculation experiments could be carried out until I should have reached that place. The cultures of the rat disease and the human plague, both, as I have stated, having been made in the same media, showed the most striking and diverse microscopic form. While the human plague existed as small more or less ovoid bacteria, most of which showed bipolar staining, the rat microbes presented larger irregularly spherical forms with some irregular filaments, and approximated to very exaggerated involution forms of plague. These latter grown in bouillon, inoculated with the merest trace of an agar culture and incubated for 24 hours, were used for the inocu-[illegible] of guinea-pigs, rabbits, pigeons, one cat, and one [illegible] These animals when inoculated each received [illegible], excepting the pigeons, one of which received five [illegible] e other only a trace.

Guinea-pigs.—The first, inoculated with another, on March 1st, died within two days. The subcutaneous tissue around the area of inoculation was occupied by an immense pale gelatinous œdema. This œdema extended from the groins over almost the whole ventral surface. The site of inoculation was almost œdematous and the track of the needle was marked by a slight hæmorrhagic exudation. The only other trace of such hæmorrhagic character was a small area 10 millimetres in diameter on the left side. The œdema was remarkably free from any hæmorrhage and was in parts about six millimetres in depth. This œdematous condition is an essential characteristic, while the absence of hæmorrhage is equally so, in all animals inoculated. The spleen was slightly enlarged, showed no white spots, and was of normal consistence. A few glands were found enlarged in the axillæ, groins, and in the mesentery. These, however, were œdematous rather than enlarged, were semi-transparent when held to the light, and emitted a semi-transparent fluid when cut into. The second guinea-pig died on the following day. Here the conditions were similar to the former, with the addition that the spleen showed white points somewhat similar to what is found in true plague and the pericardium contained some clear yellow exudation. In neither case were the lungs found to be inflamed. In other guinea-pigs similar results have been found.

Rabbits.—Two rabbits were inoculated with the original culture and two with a culture recovered from the spleen of a guinea-pig, but in neither of the cases was any illness produced. Cold abscesses were found at the seat of the inoculation which proved to be sterile. The first two rabbits were thereafter inoculated with cultures from the human plague, and in each case died from bubonic plague.

Baboon and cat.—In the cases of the baboon and cat neither were affected by the inoculation.

Pigeons.—In the case of the pigeons two were inoculated on March 26th. The one which received five drops died early on the morning of March 31st, while that which had received but a trace of the bouillon culture died on the following day. In both pigeons and guinea-pigs the rat microbes were recognised in the blood and organs, while cultures of the bacilli were also easily obtained in every case. The blood of the pigeons was in both cases most prolific in bacteria and the smallest trace transferred to agar gave rise to confluent colonies of the microbe. In the liver of the pigeon the bacteria showed greater tendency to bipolar staining than in any other situation.

Although the cultures of the rat microbe are very similar to the somewhat non-characteristic growth of plague, and although the cultures in buttered bouillon give rise to stalactite growth, yet the microscopical form of the bacteria in the body of the rat, together with its pathogenic action, are somewhat at variance with what we know of true plague bacilli. Moreover, I have had numerous opportunities of observing rats affected with bubonic plague in Port Elizabeth, but, although I have found an abundance of plague bacilli more or less virulent in action, I have not seen one case in which the rat microbe found in the early mortality at the south arm of the Cape Town Docks has reappeared. I must, therefore, until further observations have otherwise convinced me, adhere to my belief that the disease which primarily caused the mortality among the rats at the Cape Town Docks was not true bubonic plague, although being undoubtedly a variety of the bacillus of hæmorrhagic septicæmia.

Grahamstown, South Africa.

WALLINGFORD COTTAGE HOSPITAL. — This hospital, which has hitherto been very slenderly endowed, has recently received a substantial addition to its resources. The sum of £1010 has been subscribed for the purpose of endowing a bed as a memorial of the late Mrs. Helen Mary Wells, who took an untiring interest in, and rendered much active help to, the hospital from its foundation in 1878 to the time of her death in September last. During that long period she was one of its lady visitors and her cheerful presence was ever welcome to patients and officials alike. The money has been invested in Local Loans Stock in the names of the Official Trustees of Charitable Funds and a presentation brass bedstead of the Lawson Tait pattern, with a memorial plate over it, has been set up in the principal ward. A dedication service was conducted last week by the Rev. Sir J. L. Hoskyns, Bart., rural dean, when the attendance was more than sufficient to fill the ward, great interest being manifested in the proceedings, which were of a very impressive character.

SHEFFIELD ROYAL INFIRMARY.

A CASE OF STRANGULATED INGUINAL HERNIA; ENTERECTOMY; RECOVERY.

(Under the care of Mr ARTHUR CONNELL.)

IT is now generally recognised that immediate resection of the gangrenous bowel is preferable in strangulated hernia if the general condition of the patient will admit of it. Such primary resection saves the patient the risk of a second operation for closure of the fæcal fistula, and also, if the gangrenous portion is in the jejunum, it saves him from the risk of inanition which may result from insufficient absorption. It is still, however, sometimes necessary to open the [illegible] form, if the [illegible] lation appear [illegible] n would lead to a fatal issue.

A man, aged 21 years, a labourer, was admitted into the Sheffield Royal Infirmary on June 1st, 1901, suffering from symptoms of strangulated hernia. On questioning the patient the following history was elicited. Twelve months before, whilst at work, he was suddenly seized with a sense of something giving way in the abdomen, followed by violent pain and accompanied by a swelling in the left inguinal region; he immediately went to bed, the hernia being reduced by his medical attendant. Since the first attack the bowel had frequently come down, but the patient had been able to return it into the abdomen. On the present occasion, however (May 29th), the hernia was very much larger and all attempts at reduction both by himself and by his medical attendant having failed he was sent to the infirmary. On examination a very large scrotal tumour was found to be present on the left side, extending from the internal abdominal ring to the bottom of the scrotum. The skin of the scrotum and penis was markedly œdematous and ecchymosed The patient was suffering great pain, accompanied by vomiting There was neither any action of the bowels nor did he pass flatus after the descent of the bowel. The swelling was exceedingly tender to the touch, hard, tense, dull on percussion, and apparently irreducible. (No attempt at reduction was made in hospital) There was the well-marked urethral discharge of gonorrhœa present at the time

At 12 30 P.M. on June 1st Mr Connell operated Ether being administered, an incision was made along the left inguinal canal, extending from above the internal abdominal ring to one and a half inches below the external ring. On opening the sac some blood-stained serum with an offensive smell escaped; immediately the exposed region was thoroughly irrigated. The stricture was now divided and the omentum, which was very dark and found lying in front firmly adherent to the sac, was ligatured in several pieces and divided, forceps being attached to the proximal portion in order to [illegible] back into the abdomen. After [illegible] it was withdrawn from the sac [illegible] hout gloss, and on handling it it was very hard and of a leathery consistence. At the point of stricture the gut was considerably damaged and as all pulsation in the mesenteric vessels had ceased enterectomy was performed. The gut, having been clamped above and below by means of Doyen's broad ligament forceps covered with indiarubber tubing, was divided, 16 inches being sacrificed. The mesentery was divided along the line of its attachment to the gut and the bleeding vessels were clamped; little or no blood escaped from that portion of the mesentery corresponding to the blackened intestine. A continuous suture interrupted at intervals now brought the two layers of the mesentery together. The bowel being irrigated and cleaned a second time, the two ends were placed side by side and united by immediate suture—one set of continuous sutures interrupted twice for the mucous membrane and a second set of the same type for the sero-muscular coat The super-abundant mesentery, falling into natural folds on suturing the gut, was sutured after the manner suggested by MacCormac. The parts were reduced after careful overhauling and the operation was completed as for inguinal hernia. Recovery was uneventful, the patient leaving the infirmary on June 22nd feeling quite well. Flatus was passed during the night of the 1st

Remarks by Mr. CONNELL.—One is not often called upon nowadays to operate in such advanced cases of strangulation in external hernia, except, perhaps, in some cases of femoral hernia which are attended with unusually rapid pathological changes, and I venture to place on record this case which was somewhat acute. That the condition of the gut (small intestine) found at the operation after three days' strangulation should be so far advanced was, to say the least of it, surprising, but may be accounted for perhaps by the following factors acting together—(1) the congenital type of the sac; (2) the presence of a large quantity of omentum in [illegible] for strangulated hernia are attended with a high mortality, and it is not surprising when one considers the auto-intoxication which takes place where the vomiting has become stercoral, as in this case Fortunately for this man, his powers of resistance were in evidence and played no inconsiderable part in the recovery. It is a pleasure to me to express my indebtedness to Dr. John Broadley, the house surgeon, for the notes and for the great care and *attention of the patient after the operation.*

Reviews and Notices of Books.

Introduction to the Study of Medicine By G. H. ROGER. Authorised translation by M S GABRIEL, M.D, with additions by the author. London: Henry Kimpton. 1901. Pp 550 Price 21s

THE translation which we have before us is a reproduction in English of the course of lectures delivered by Professor Roger at the University of Paris during the year 1897-98 This course of lectures was instituted by the faculty of the university as a means of introducing to students at the commencement of their professional education the principles and aims which should guide them in the subsequent pursuit of scientific knowledge To read these lectures is to admit that Professor Roger has fulfilled this object in the most admirable manner In view of the remarkable advances witnessed during the last decade in what may be called the technique of laboratory diagnosis it is interesting to note the following pronouncement on the part of the author, who is no less famous for original research in the laboratory than for success as a practical clinician "It seemed to me important to oppose the tendency of some modern authors who think that the solution of problems raised by the examination of patients can be found in laboratory researches. No one is more firmly convinced than myself of the usefulness of experimental pathology; nevertheless, at the bedside the physician can do no better than to depend upon clinical procedures Only in quite rare instances will he be obliged to resort to more delicate methods of investigation. I cannot admit abdication of clinical methods before the rising tide of bacteriology" It is clear to the careful reader that this is the underlying "motive" throughout these lectures and the considerable space—some 200 pages—which is devoted to the examination of the sick at the bedside is convincing proof that the unaided application of the senses can lead to practical results in diagnosis

The arrangement of the various sections is simple and methodical. In the early chapters the student is introduced to the causes which interfere with the physiological processes of life; those that follow explain the reaction of the organism to these external causes and introduce the reader to the essentials of morbid anatomy and the objective and subjective manifestations of disease. From the beginner's point of view it is probable that the chapters which deal with the examination of the sick will prove of the greatest value, while advanced students and practitioners will appreciate more highly the philosophic representation of the processes of general nutrition, the auto-intoxications under normal and abnormal conditions, the significance of diatheses, the pathology of the fœtus, and the influence of heredity. With regard to diatheses, the reader will notice that Professor Roger follows closely the teaching of Bouchard. He rejects the conception of tuberculous, syphilitic, cancerous, and other diatheses, and admits of two only—namely, the scrofulous and the arthritic. He defines a diathesis as a particular mode of nutrition: arthritism as a sluggishness of nutrition, scrofulosis as a failure of carbohydrate and nitrogenous assimilation. The effect of these particular forms of metabolism is to induce morphological characteristics and pathological processes of nutrition which are easily recognisable in individuals who conform to one or other of the above types. Arthritism is the inheritance of civilised people and of the upper classes. Most individuals with a superior intelligence are tainted with it. Scrofulosis is found in children born of parents in bad health suffering from some chronic intoxication; they are weaklings with flaccid muscles, long and silky eyelashes, hypertrophied tonsils, and wide noses. These nutritive disorders, whether the result of infective or autochthonous intoxication, may be transmitted to the children, but the most serious manifestations of such failures of metabolism are not necessarily perpetuated in descent; healthy surroundings for mind and body may retard or even definitely prevent the display of the worst features of such hereditary taint, they may only become apparent under the influence of the appropriate stimulus—in other words, they are preventable.

The few pages which are devoted to the consideration of genius, insanity, and crime are intensely interesting and suggestive. The views of the author are not absolutely in harmony with those of Lombroso and his school on the mutual relationship of these mental conditions. Professor Roger, while admitting that there are affinities between genius and insanity on the one hand and between insanity and crime on the other, will hear of none between criminality and genius. He considers that men of genius are superior degenerates, criminals to be inferior degenerates. Genius and crime are the two converging (or diverging) sides of an angle which has insanity for its apex. This is the only point at which these lines meet; the further they are extended the more divergent they become. These are but a few of the interesting problems which the author tries to solve in words which can be understood by an audience only imperfectly equipped with a knowledge of medicine. But for both student and practitioner this introduction to the study of medicine is, indeed, as the translator expresses it, "a fascinating journey into the regions of medicine where the most important developments have recently been realised." In conclusion, we must congratulate Dr. Gabriel upon the successful manner in which his translation reflects the brilliant literary style of the original text.

The Cambridge Natural History. Edited by S. F. HARMER, F.R.S., and A. E. SHIPLEY, M.A. Vol. VIII.: Amphibia and Reptiles. By Dr. HANS GADOW, F.R.S. London: Macmillan and Co. 1901. Pp. xiii.-668. One coloured plate and 181 figures in the text. Price 17*s.* net.

DR. GADOW has done his best to disprove at least the latter half of one of Linnæus's crisp phrases which he quotes in his preface. "Amphibiologi," wrote Linnæus, "omnium paucissimi sunt nullique veri." Dr. Gadow has in his lengthy volume given us an account of both amphibia and reptiles which should satisfy the expert zoologist and at the same time entertain the reader who is merely interested in the tit-bits of natural history. Much that Dr. Gadow has to say will be new to most readers, and all, so far as we have tested him, will be found to be true. Besides, he is an expert in the groups of which he treats, more particularly of the reptiles; and this is precisely the most satisfactory character about this and the other volumes of the Cambridge Natural History; we can always follow our instructor with confidence, for which we have to thank the editors of the series.

The gentlemen entrusted with the editing of the Cambridge Natural History have been wise in not insisting upon long disquisitions upon toads immured in limestone rocks of the carboniferous period, upon vipers swallowing their young, upon the sea-serpent, and those various topics so intimately connected with the animals treated of in the present volume which appeal so strongly to the "energetically ignorant" In spite of these omissions, or scant and uncourteous references, Dr. Gadow's volume will be found to be in the proper sense of the word "popular." There is not an anecdote told of frog, toad, or lizard that has not a definite and important fact to state or to explain. There is an entire absence of that tiresome facetiousness sometimes supposed to be necessary in dealing with natural history. Instead of this we find an easy and by no means monotonous account of the ways and life histories of a large series of amphibia and reptiles. A considerable portion of the book is naturally anatomical. And here Dr. Gadow is on familiar ground, constantly traversed and retraversed by himself in his own investigations; even those sections which deal with "bionomics" are by no means mere quotations from the observations of others. A large number of amphibians and reptiles of many kinds have been kept by the author and carefully noted and surveyed. The result is a book full of accurate information and pleasant reading. Dr. Gadow does not commit himself much to theory; he deals warily with many controversial points. Fierce and frequent have been the discussions of late concerning the meaning of many facts in animal colouration. In no branch of biology, perhaps, has theory so completely out-distanced fact. It has been asserted that the proteus, that singular blind and white newt-like creature inhabiting the caves of Adelsberg, owes its loss of colour to the absence of necessity for any particular colouration in a locality where there is no one to appreciate it. The useless colour, like the useless eyes, have, it is held, disappeared for this reason. To suggest a plain and homely action on the part of environmental forces was to become the very worst kind of heretic And yet Dr. Gadow quotes Mr. Bles to the effect that the proteus when removed from its caverns and made to live a reasonable out-door life "turns ultimately jet-black." The changes of colour of the chameleon have engaged the attention of naturalists as well as of poets. Some of the former have attempted to insinuate that these changes are mainly, if not entirely, for protective purposes. Excitement, anger, cold, and heat seem to be at least as potent factors in determining a change of hue, and Dr. Gadow thinks that "adaptation to their immediate surroundings takes place to a very moderate degree only."

Much has been written, especially in America and by the late Professor Cope and Professor Marsh, of those often monstrous creatures of the Mesozoic period—the dinosaurs The great interest attaching to these archaic reptiles is naturally their supposed relationship, indeed alleged ancestry, to the modern birds. To the late Professor Kitchen Parker it appeared ridiculous that an 80-feet dinosaur wallowing in oolitic mud should have given rise to that tiny pinch of feathers called a humming bird. But after all the shock to the sense of fitness of things is not very much greater than that inflicted by the certainty that the extinct New Zealand moa towering over the tree ferns is most unquestionably of common origin with the same humming bird. Size is not a difficulty in judging relationships. The real difficulty in this matter is plainly put by Dr. Gadow. The earliest bird—the familiar, even notorious, archæopteryx—is in almost every sense of the word a bird of the most unmistakeable kind. As the dinosaurs antecedent to this bird with its mediæval hand show no indications whatever of an approach to the bird type of structure greater than those shown by dinosaurs contemporaneous with or subsequent to the archæopteryx it seems inconceivable that we are to look for the avian tree in this direction. The dinosaurian suggestion is undoubtedly strengthened by the greater probability that they were warm-blooded and had air-sacs like birds, but it is nevertheless merely tantalising in the present state of our knowledge. This group of reptiles is one of the best instances of a dominant group. They ranged in size from that of a crow to perfectly gigantic proportions and showed much variability of structure and naturally concomitant variability of habit. Why they disappeared is one of those puzzles which there are at present no data to explain. It seems impossible that the tiny mammals which began to appear in their day with their defenceless bodies and slinking ways can have got the better of them in the struggle for existence. In default of any better explanation we must have recourse to such comfort as we can get out of the homely saying, "Every dog has his day."

The chapter on Snakes and their Poison will naturally appeal to many of the readers of this review. The actual symptoms are detailed in the case of several of the more venomous species, and these details are extracted from Professor Clifford Allbutt's "System of Medicine." Dr. Gadow says that several species of birds and mammals are "immune by nature" against the poison of serpents. This matter is one of very great interest, but we had thought that "mithradatism," as it has been proposed to call this fortunate disposition after the unpoisonable king of Pontus, was more usually replaced by special activity on the part of the snake-eating creature. The mungoose, for example, which was imported at one time into Santa Lucia and some other islands of the West Indies to cope with the fell trigonocephalus, is, at least by many, believed to owe its apparent immunity to its agile way of leaping aside from the serpent and then at the right moment leaping with equal agility upon the back of its head. There is, of course, the legend that the mungoose when bitten eats of a particular herb which at once neutralises the venom, but this suggestion does not, we should imagine, demand serious discussion in these columns. A highly disconcerting habit of many of the viperidæ is related by Dr. Gadow. It appears that the common English viper and the asp which bit Cleopatra, cerastes, have the uncomfortable habit, not possessed by other beasts of prey, of being attracted by the camp fire. Dr. Gadow combats the superstition that the rings on the "rattle" of the rattlesnake have anything to do with its age; they are not at all, as some think, comparable to the rings of trees in their significance of age. They are, however, useful to the casual stroller in American forests by warning him of the presence of their deadly owner, a circumstance which might appear at first sight a little too altruistic for adoption by Nature. It must be remembered, however, that the advantage is probably mutual; the snake does not want to be trodden upon although it may bruise the heel of the traveller by way of a retort. Dr. Gadow does not mention an interesting analogy pointed out some years ago by Dr. Günther between the tail of the rattlesnake and that of the porcupine. In both creatures there is a rattling and warning apparatus upon the tail which is in both formed of hardened epidermic structures.

We have picked out a few matters from this solid but easily assimilable volume for the purpose of illustrating its exceedingly thorough nature. Its usefulness and interest to the general reading public is much increased by the numerous figures, many of them new and prepared specially for this volume by the skilful pencil of Miss Bateson who has in most cases drawn her subjects from the life and in characteristic attitudes.

Public Water Supplies, Requirements, Resources, and the Construction of Works. By F. E. TURNEAURE, C.E., Professor of Bridge and Sanitary Engineering, and H. L. RUSSELL, Ph.D., Professor of Bacteriology, University of Wisconsin, with a Chapter on Pumping Machinery by D. W. MEAD, C.E., M. Am. Soc. C.E., &c. First edition. New York: John Wiley and Son. London: Chapman and Hall, Limited. 1901. Pp. 750. Price $5.

IT may be well to give a general outline of the scope of this book which deals chiefly with the conditions found in the northern part of America.

In the preface there is a brief introductory chapter which will be referred to presently. The main body of the work is divided into two parts. Part I. deals with Requirements and Resources and Part II. with the Construction of Waterworks. A study of the book shows that by "resources" the authors refer to the sources of supply, and this part of the book contains chapters on Rainfall, on Evaporation and Percolation, on the Flow of Streams, and on Ground-water. The second section of Part I. deals with the Examination of Water-supplies, with the Quality of Water derived from Various Sources, and with the Connexion between Water-Supplies and Communicable Diseases. In dealing with the quantity of water required the authors give tables showing the amount which is consumed per head in the case of many cities. Although few towns in the United States use any considerable amount of water for ornamental purposes, yet the total amount which is said to be supplied is very great, and it may be not without interest to notice the time of the day during which the greatest amount of water is used. A table is given of the rate of consumption in Boston, Massachusetts. The smallest amount is taken between the hours of from 1 A.M. to 4 A.M., but the rate at which water is supplied during that time amounts to no less than 40·8 gallons per head per day. The greatest amount is used between 7 A.M. and 10 A.M., and during these hours the rate is that of 103·8 gallons per head per day. The average amount taken per day is 73·6 gallons per head. It seems possible that a large proportion of the water is lost in American cities through defective mains, and in favour of this hypothesis it may be stated that the authors of the book under review state that one engineer "specifies" the maximum of "allowable leakage" to be from 60 gallons to 80 gallons per mile per inch of diameter of pipe, and another engineer showed that a leakage of 6400 gallons per head per mile took place from a 24 inch pipe under a pressure of 110 pounds per square inch. It is stated also that cases of breaches of four inch and six inch mains have remained undiscovered for a long time and that the water has flowed away through adjacent sewers to the amount of 100,000 gallons in 24 hours. Another cause of the greatness of the amount of water used in American cities appears to be that taps are often allowed to run continually. This practice is extremely common during the cold weather and it is adopted as a means of preventing freezing of the water in the pipes within the houses.

A table given in regard to the sources of water-supplies in the United States is of some interest. It appears that out of a total of 3356 organised supplies given 33·2 are derived from surface waters, that is to say, from rivers, from lakes, from impounding reservoirs, or by some combination of these different sources. Ground waters are used in 54·2 per cent. of the supplies. This figure is made up in the following way: shallow wells, 25·7 per cent., artesian wells, 10·1 per cent.;

springs, 14·9 per cent.; galleries and tunnels, 1 per cent.; and a combination of these different systems, 2·5 per cent. Surface and ground-waters—that is to say, a combination of the two chief classes given above—are used in 7 6 per cent. of the total organised supplies, and this number is made up as follows: rivers and ground-waters, 6·1 per cent.; lakes and ground-waters, 0 9 per cent.; and impounding reservoirs and ground-waters, 0·5 per cent.

Dr. Russell is responsible for the chapters on the Examination of the Water-supplies, for the one which deals with the Quality of the Water, and for one on the Spread of Communicable Diseases by Means of Water-supplies. In these chapters an account of the methods of physical examination employed in estimating the purity of the water is given and there are details concerning its chemical, bacteriological, and microscopical examination. The importance of sanitary surveys of the sources of supply also receives some consideration. The quality of "meteoric" surface and subterranean waters is discussed and there are remarks on the effect of the storage of water. The chapter specially devoted to the question of the spread of diseases which are usually disseminated by water contains accounts of epidemics of typhoid fever, of cholera, and of anthrax. The author does not show any knowledge of the work which was done by William Budd and by John Snow in regard to the spread of communicable disease by water, and a study of this part of the work lends support to the belief that the English literature on this subject is not generally familiar to American writers.

The part of the book which deals with the collection of water contains chapters on impounding reservoirs, on earthen embankments, on masonry dams, and on timber dams. The means adopted for the purification of water are dealt with at some length in the chapters on Sedimentation, Sand Filtration, Mechanical Filtration, and Miscellaneous Purification Processes. In regard to sand filtration Dr. Russell, who is responsible for this chapter, makes the remarkable statement that it is interesting and valuable to note that this process was developed empirically. As a matter of fact, the work undertaken by Mr. James Simpson for the Chelsea Waterworks Company and the results at which he arrived were by no means empirical. The work which it was desired to do was to remove from Thames water the grosser impurities, and after a series of investigations Mr. Simpson perfected a filter bed which accomplished the purpose he had in view and which formed a model from which but little modification has taken place since. The chapter on Sedimentation contains some account of observations which are of considerable interest. It is said on the authority of Fuller that the sediment contained in the Ohio river varies from one part to 5000 parts per million, that the ordinary range of variation is from 100 parts to 1000 parts, and that the number of bacteria varies from a few hundreds to 50,000 per cubic centimetre. The size of the particles held in suspension varies greatly. Suspended particles when the water is at rest carry down with them a number of bacteria. Dr. Russell remarks that sedimentation as a purifying process has long been known in England. This is true. The process of sedimentation was used for the purification of water in England for centuries before America was discovered by Columbus.

It does not appear necessary to do more than to indicate the arrangement of the information which is given in regard to the Distribution of Water. It is dealt with in chapters which refer to pipes, to conduits, to pumping machinery, and to reservoirs. A few words must, however, be said with regard to the historical sketch with which the book commences. The authors touch upon such interesting subjects as Jacob's Well at Cairo, the wells of Greece, of Syria, of Persia, and of China. They reproduce illustrations of the Roman aqueducts which have already appeared in a book by Mr. Herschel. This engineer, it may be remarked, made a calculation as to the amount of water which was formerly supplied to Rome and his results are adopted by the writers of the present book. It may, therefore, be worth while to state that the data upon which Mr. Herschel formed his conclusions were not sufficient for the purpose. The information given in regard to the water-supply of London is not great in amount—a matter, perhaps, which hardly calls for regret. The authors state that "in London various pumps were erected on the bridge [London Bridge] from time to time which drew their supply from the river and were operated by the current." The pumps were not erected on London Bridge. They were worked ("operated") by water-wheels. In the next sentence it is stated that in 1819 the New River Company was incorporated and laid its pipes throughout the City. It is not correct to say that the New River Company laid pipes throughout the City in that year. At that time the extension of the supply of the company was made from time to time as new customers were obtained. In the next sentence it is stated that "it"—that is to say, the New River Company—"received its supply from the New River." This is true. The authors, however, do not appear to know that the New River was a conduit made for the express purpose of conveying water from Amwell and Chadwell, two Hertfordshire springs, to London. The book is well printed, but the spelling differs from that adopted in this country.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

AN ordinary meeting of the Comitia was held on July 25th, Sir W. S. CHURCH, Bart., the President, being in the chair.

The following gentlemen having passed the required examination were admitted as Members: Thomas Bushby, M.B. Edin.; Arthur Henry Weiss Clemow, M.D. Edin.; John Cecil Mackmurdo Given, M.D. Lond.; Thomas Wardrop Griffith, M.D. Aberd.; Arthur Douglas Heath, M.D. Lond., L.R.C.P.; Thomas McCrae, M.B. Toronto, L.R.C.P.; Frederick Craven Moore, M.D. Vict.; and Harold Douglas Singer, M.D. Lond., L.R.C.P.

Licences to practise were granted to 112 gentlemen who had duly satisfied the examiners, and Diplomas in Public Health were granted, conjointly with the Royal College of Surgeons of England, to 24 gentlemen.

William Joseph Tyson, M.D. Durh., elected April 25th, was admitted to the Fellowship.

The following communications were received:—1 From the secretary of the Royal College of Surgeons of England reporting certain proceedings of the Council on July 11th. 2. From Dr. F. Womack, lecturer on physics at St. Bartholomew's Hospital, suggesting some amendments in the Syllabus of Physics for the first examination.

The PRESIDENT announced that Dr. Norman Moore had been selected as Harveian Orator.

A report was received from the Council in regard to the desirability of the representatives of the College on the Senate of the University being *ex-officio* members of Council, making the following recommendations:—1. That of the two representatives of the College on the Senate of the University of London one be *ex-officio* a member of Council. 2. That each representative serve alternately as a member of Council for a term of two years or for such shorter term as he may remain a representative; and that in the first instance, of the two representatives the senior Fellow be the one to serve.

On the recommendation of the Council the Baly Medal was awarded to Frederick William Pavy, M.D. Lond., F.R.S., F.R.C.P., for his researches on "The Physiology of the Carbohydrates: their Application as Food, and Relation to Diabetes," 1894, but more especially for his original investigations on Sugar Formation in the Liver, which he has carried on during the last 40 years and with unabated enthusiasm during the last two years.

Reports were also received: (1) from the representative of the College in the General Medical Council on the proceedings of that Council during its session in May last; (2) from the Committee of Management; (3) from the Conjoint Finance Committee; (4) the quarterly report of the College Finance

Committee; (5) the annual report of the Library Committee; and (6) the annual report of the curators of the museum.

The REGISTRAR moved that the by-laws in conformity with the revised regulations of the Conjoint Board, adopted May 9th, 1901, be re-enacted for the second time. Books and other publications presented to the library during the past quarter were received and thanks returned to the donors.

The following is a list of the Censors and other officers nominated by the President and Council and elected for the ensuing year 1901:—Censors: Dr. Thomas Tillyer Whipham, Sir Dyce Duckworth, Dr. Thomas Henry Green, and Dr. George Vivian Poore. Treasurer: Sir Dyce Duckworth. Emeritus Registrar: Sir Henry Alfred Pitman. Registrar: Dr. Edward Liveing. Harveian Librarian: Dr. Joseph Frank Payne. Elected Members of the Library Committee: Dr. Samuel Gee, Dr. John Wickham Legg, Dr. Norman Moore, and Dr. William Henry Allchin. Curators of the Museum: Dr. William Howship Dickinson, Dr. Henry Charlton Bastian, Dr. William Cayley, and Dr. John Abercrombie. Finance Committee: Dr. Thomas Tillyer Whipham, Dr. Alfred Lewis Galabin, and Dr. Stephen Mackenzie.

EPSOM COLLEGE: FOUNDER'S DAY.

THERE was, as usual, a large and representative assembly of members of the medical profession at Epsom College on July 27th, when Founder's Day was celebrated, the annual distribution of prizes being also associated with the celebration. The proceedings commenced with a thanksgiving service in the chapel, after which the visitors adjourned to the big schoolroom. The head-master, the Rev. T. N. Hart Smith, presided, and was supported on the platform by the chairman of the council, Sir Joseph Fayrer, Sir Herbert Maxwell, M.P., Dr. C. Holman (treasurer), Colonel Gordon Watson, son-in-law of the founder, and the members of the school staff. The head-master having welcomed the visitors referred to the death of the late Queen and mentioned that she had been a patron of the institution eve [illegible]

always taken a great interest ir

but it was a great consolation,

pleasure of announcing it that day, that the King had kindly consented to take her place and become the patron. His Majesty was present at the opening of the college; he visited it five or six years ago, when the foundation-stones of the lower school were laid; and he had added to his kindness by becoming their patron and continuing his interest in it in that way. He never remembered more entries than they had had that summer term, and certainly, so far as examinations were a test of success, they had never had a more successful time than during the last 12 months. He hoped that this year the result might be improved upon because they had entered no less than 58 boys. Referring to Lord Rosebery's speech at the recent festival dinner he observed that a great many of them sympathised with his lordship's allusion to the rather long adjectives with which their title was burdened. He thought they would be very much amused if he were to tell them some of the results of one of those adjectives. He was often asked by anxious parents if he would train their son, who was going to become a doctor, in anatomy, materia medica, or put him through his bones. Sometimes he received advertisements of strange appliances or gruesome drugs, but what gave him more satisfaction, perhaps, than anything else was to be addressed as the dean of the medical school.—The prizes were then presented.

Sir HERBERT MAXWELL, M.P., afterwards addressed the assembly and in the course of his remarks observed that he had a hobby and that hobby was natural history. He noticed that amongst the prizes was one given for proficiency in that science and he was glad to see that it had its place amongst their studies. But his satisfaction was somewhat damped when he found that that prize was awarded, not for reports of successful research, but for competition collections. He was aware of his boldness in making that criticism, but he would not be quite sincere if he concealed from them the regret that he had that natural science seemed inseparable from competition and from the destruction of the very creatures which naturalists ought most to admire, to revere, and to protect. What did a competitive collection imply—a collection of butterflies, a collection of birds' eggs, a collection of dried plants? Did it not mean the destruction of the specimens, and that those specimens were valued just in proportion to their rarity? They were a populous nation, and as man increased the humbler animals, the humbler organisms, were apt to decrease. Let natural history and that love of open-air pursuits be increased to the utmost—nothing but good could come of them; but would it not be possible, he asked, rather than to bestow prizes upon successful collectors to offer them to stimulate the industry and penetration of careful observers? It seemed to him that the difference between the love of excelling and the love of excellence was the difference between the mere collector, the competitive collector, and the student of nature who loved nature and all its works for their own sakes.

The usual votes of thanks concluded the proceedings.

ASYLUM REPORTS.

Worcester County and City Asylum (Annual Report for 1900).—The average number of patients resident during the year was 1144 and comprised 516 males and 628 females. During the year 247 patients were admitted, 129 being males and 118 being females. Of these 31 were not first admissions. Mr. G. M. P. Braine-Hartnell, the medical superintendent, states in his report that among the admissions there were 160 patients in indifferent health and reduced condition and 69 patients in bad health and exhausted condition. One male patient was admitted suffering from pneumonia which caused his death in four days, and two patients (one male and one female) were admitted with recently-cut throats, both recovering in a few days. During the year 77 patients were discharged as recovered, or 6·7 per cent. of the average number resident. The deaths during the year amounted to 128—viz., 57 males and 71 females—or 11·18 per cent. as calculated on the same basis. 30 per cent. of the deaths were in patients of 70 years of age and upwards. General paralysis was responsible for 17 deaths, pneumonia for 26, and phthisis for 26. These three diseases caused more than half of the total deaths. Post-mortem examinations were made in 110 cases of death. A married woman admitted while pregnant was confined of a daughter. The patient died soon afterwards from pneumonia. An inquest was held on the body of a female patient who had escaped and drowned herself in the reservoir. The jury returned a verdict of "suicide by drowning," and added "that no blame attached to anyone connected with the asylum." This is the first case of suicide which has occurred in the asylum since 1883. Four male patients escaped from the asylum. One was recaptured in four hours and another in three days. Two remained at large and at the expiration of the statutory period were regarded as discharged. Colitis or dysentery still prevailed, being associated partly with overcrowding and partly with feeble health. Two male attendants were called out to join the army in South Africa. Their places are kept open for them in view of their return. Two male attendants were dismissed for striking patients and were prosecuted by the committee. They were each fined 40s. and costs. With these exceptions the conduct of the staff has been satisfactory. The average weekly cost per patient for the year was 8s. 0½d. This is 2¾d. more than last year, and the increased price of coal is responsible for this. The profit on the farm amounted to £533 8s. 0d. "In view of the constant recurrence of infectious disease a good disinfector is urgently needed. The present means of disinfection are antiquated and inadequate and a source of anxiety." The Commissioners in Lunacy state in their report that the wards were bright and cheerful, the dormitories were in good order, and the bedding was very clean. The case-books and other medical records were carefully and intelligently kept. In view of the overcrowding of the asylum a site for a new building has been obtained near Bromsgrove, and the Commissioners recommend that rooms should be arranged in it for idiot children apart from insane adults.

THE LANCET.

LONDON: SATURDAY, AUGUST 3, 1901.

The British Medical Association: The Address in Medicine.

DR. J. F. GOODHART took for his subject the difficulties encountered in the daily practice of medicine, and seldom have we listened to a more eloquent discourse. The first difficulties with which Dr. GOODHART dealt emanate from the patient. In spite of the enormous advances made by medicine and surgery it cannot be said that drugs are less used or operations less frequent. The reason for this lack of diminution of medical treatment is to be attributed to the increased sensitiveness about health displayed by civilised peoples. This has necessarily its good side, and so far as it leads to increased care in the prevention of disease or to greater appreciation of early treatment in serious maladies, it works for good; but the patient is daily becoming more sensitive to many minor ailments which would right themselves without any aid from the pharmacopœia. The patient also wants to know too much, and will have a name for his ailment, even though the name alone can tell him nothing. Should his medical man be unable to give an exact diagnosis it is taken as a proof of ignorance and a practitioner who is more rapid at naming the disorder is called in. Yet there are no departments of medicine where hesitation is so great a proof of knowledge as in diagnosis. It is true that wide knowledge may recognise at once conditions which have puzzled those less learned, but it is also true that he who knows much may hesitate long in coming to a conclusion, while he whose knowledge is limited, having fewer matters among which to choose, hastily makes a diagnosis. Yet this is quite unappreciated by the average patient who estimates the value of an opinion by the certainty with which it is expressed. Dr. GOODHART showed also the mistaken notion that too many patients have of the nature of a consultation—viz., that the second opinion is sought to set the first right; even though the second opinion serves in probably a majority of cases to confirm the diagnosis already given, for nowadays the general high level of medical education makes it rare indeed for any great error to occur. The knowledge of the laity of the names and uses of drugs is not extensive, but yet deserves to be considered of that degree which is dangerous; for the patient with a little therapeutical learning tries all the new preparations on himself, and only when he has tried them in vain does he condescend to consult a medical man.

The patient, however, is not alone to blame for much that is unsatisfactory in the practice of medicine: the medical man himself is responsible for no small part of the attitude of the laity, and Dr. GOODHART does not spare the profession. We are too ready, he told us, to detect disease, for we do not appreciate how wide are the limits of health, how many deviations from what we call the normal are compatible with a good state of health. The two organs with which the statement of this fact was illustrated were the heart and the stomach. The heart is often said to be weak and its owner is cautioned against exertion, and in consequence he leads a useless, indolent life, when the heart would have been all the better for a reasonable amount of work. Indeed it may well be that lack of work may impair the vitality of a heart which but for excessive care would have lasted many years and performed its duties well. The stomach, too, is often needlessly maligned. Catarrh and dilatation are frequently said to be present on insufficient grounds and unnecessary treatment is prescribed for what has never existed. Excessive mobility of the abdominal viscera is often diagnosed nowadays and various stitching operations are recommended. Not rarely the demand for the operation comes from the patient, who knows, or has heard of, someone else on whom it has been performed, and there is often great difficulty in persuading such an one that no operation is needed. And if the patient has a liking for an operation he has a still greater relish for drugs, of which he can consume an enormous quantity. No treatment is thought to be complete unless a prescription is given, and it is, perhaps, because of the universal presence of drugs in some form or other in every case that the laity have got the idea into their minds that the drug is the essential part of the treatment and that the advice as to diet and habits is merely a customary addition of very little importance. The advice may be priceless, yet if it is unaccompanied by the prescription it is thought to be of very little value.

Dr. GOODHART had a word to say on fashion in drugs, and it must be confessed with humility that there is a fashion in drugs which is comparable with nothing so much as with fashion in dress. Drugs which but yesterday were extensively used are to-day almost forgotten. The antipyretics which were prescribed so freely 15 years ago are hardly ever given now for their effect on temperature, though the more important members of the group are given still, but for entirely different reasons. The drugs which at the present moment appear to be at the height of their popularity are animal extracts and antitoxins, yet the discerning eye may even now perceive that many of them have passed their zenith and ere long will be forgotten, or at most will be employed only in rare and isolated cases. There is much excuse to be made for the mental attitude of extreme hopefulness with which we receive each new medicament, for there are still so many diseases and symptoms appealing for help and we have to acknowledge that we can do but little for them. Yet it would be well if we adopted a more cautious attitude in receiving new drugs and new methods of treatment; they deserve to be tried and to be tried thoroughly, but we must not expect too much and must sift carefully the evidence for and against them. When we have tried and proved the value of any treatment let us hold fast to it and not too hastily throw it aside for some more novel, yet possibly less useful, method. In the hands of the medical man rests the power of educating the public mind to appreciate the value of medical advice and the less importance of drugs.

If the medical profession insists strongly on this their patients will in time come to put a higher value on the medical advice of which at present they think but little.

◆

The British Medical Association: The Address in Surgery.

THE surgical lessons of the campaign in South Africa formed the subject of Sir WILLIAM THOMSON'S Address in Surgery. Many of these lessons have been much taken to heart by the medical profession as they were learned from the communications to our columns and those of the *British Medical Journal*, but the teachings of the war will bear recapitulation for South African experiences have had a revolutionary effect on the tenets of military surgery. Moreover, Sir WILLIAM THOMSON made his points with great clearness speaking with the authority of first hand knowledge. The conditions were novel under which that campaign was fought, so that it was difficult to foretell exactly what surgical lesions would be met with. The chief changes in the conditions were the smaller size of the bullet its greatly increased velocity, and its inclosure in a smooth nickel casing. Experiments made beforehand, and a few accidents enabled surgeons to have some idea as to the results which would be likely to follow, but all the experiments were on dead bodies, chiefly of cattle, and dead tissues do not react to the passage of a bullet in the same manner as living tissues react. The experiences of the Cuban War, fought under somewhat similar conditions were hardly available for very little had been published either by American or Spanish authorities at the time when hostilities commenced at the Cape.

There are two main points which have to be considered before the probable damage inflicted by modern high velocity bullets can be estimated —firstly the distance at which the rifle is discharged and secondly, whether or not the bullet meets with a bone in its passage through the tissues. If the rifle is fired within 200 yards the destruction produced is very great indeed, even if no bone be broken but the vast majority of the shots were fired at a much greater distance than this and these severe results were rare. When the bullet encounters no bone in its passage through the tissues it is marvellous how very slight may be the disturbance. A minute aperture of entry is made decidedly less than the size of the bullet, and the aperture of exit can be barely distinguished from it. So smooth so polished is the surface of the projectile that it makes its way among the structures more by pushing them aside than by tearing through them, so that after the bullet has passed the displaced tissues fall back naturally into position and no channel is left. Therefore if no septic organisms have gained admittance the parts are in the most perfect order for the occurrence of rapid healing. It might be thought that the tissues displaced by the bullet were severely damaged and prone to slough, but a case in which the cartilages of the nose were perforated showed that a mere fragment of tissue nearly cut off from all its vascular connexions by the bullet may survive. Whether the projectile were aseptic or not it is certain that many gunshot wounds healed by first intention. This does not, of course, prove that they were absolutely aseptic but it proves that very few organisms can have been present—no more than the tissues could deal with. The early application of the first dressing Sir WILLIAM THOMSON considers to have been a factor of great importance in the rapid healing of wounds. This first dressing was often applied by the wounded man himself and therefore morbid germs had but little chance of entering except when they were carried in by the bullet. Another cause of great moment in the healing of the wounds was the dry atmosphere by which any blood or other exudation quickly dried into a scab, this condition of the atmosphere was doubtlessly in great part due to the elevation of 4000 feet or more which characterised a large portion of the seat of war. All the conditions for the healing of the less severe wounds could hardly have been more favourable.

Even when the bullet traversed the abdomen the injury done was wonderfully small. It appears to be proved that a Mauser bullet can pass between coils of bowel without wounding them for one case was met with by Mr CHEATLE in which the bullet passed through the cæcum and sigmoid flexure without wounding the intervening small intestine. Other cases however have been recorded in which after the passage of a bullet through the abdomen blood in the motions proved conclusively that the bowel had been wounded. Yet even in some of these cases an uneventful recovery followed without any operative interference. This Sir WILLIAM THOMSON considers was due to the angle of impact being nearly 90 degrees. The inducements therefore to perform primary laparotomies were not great when so many cases of perforating abdominal wounds recovered without operation and the want of facilities for abdominal surgery made it very inadvisable to perform abdominal section except in a small minority of cases. Even where perforation and extravasation have obviously occurred it is generally not possible to operate for the elaborate procedures and the aseptic conditions necessary for the successful performance of a laparotomy are not to be found in most field hospitals and probably will not be found for many years.

The greatest difference however between the injury inflicted by the older large soft, slowly travelling bullets and the modern small hard and rapid projectiles is to be found in the injury sustained by the bones. When a modern small bore bullet meets the shaft of a long bone it comminutes the bone and many of the fragments are carried some distance in the direction in which the bullet was travelling. These fragments tend to cause extensive destruction of the soft parts. If the velocity of the projectile is less the injury to the bone is slighter and may cause only a single fracture. When however, cancellous bone is encountered by the bullet a clear perforation of the bone not infrequently results. The statistics of the American Civil War demonstrate conclusively the very large proportion of cases in which bones are broken in warfare nearly 25 per cent. of the wounded in the Northern hospitals suffered from fractures. Formerly the mortality was appalling and the benefit resulting from amputation in gunshot fractures of the limb-bones was very problematical, for after amputation of the thigh in the Crimean War 73 per cent. died, and in the Franco-German War among the French wounded the mortality reached 90 per cent. The treatment of these cases without amputation was able to show somewhat better results even in the earlier wars, and in the Franco-German War the difference was marked. In the recent fighting in Cuba the general mortality of all cases of compound fractures of the thigh was under 11 per cent. In the South African campaign general numerical results are not yet attainable, but Sir WILLIAM THOMSON tells us that amputation was quite exceptional and only performed when the case was otherwise hopeless, yet the total mortality was exceedingly small. Wounds of joints also have done well. The old teaching was that whenever the knee-joint was penetrated by a bullet, whether the bone was fractured or not, the limb should be amputated, and this doctrine was supported by the experience of the Crimean War and the American War. Yet in the present war the cases did extremely well without amputation; most of them pursued an aseptic course, and by careful occlusion of the openings and keeping the limb at rest, recovery, and in many cases early restoration of normal movement, followed.

The South African War has demonstrated the urgent importance of not exploring wounds on the field of battle, or, indeed, at any time, unless there is a distinct indication for it. It has shown that elaborate operations are not possible with the present arrangements, at least in field hospitals, neither are they needed in many injuries in which formerly they were considered absolutely necessary. The slighter injuries heal readily, simply, and as a rule aseptically, with almost a minimum of treatment. What changes in military weapons time may bring we cannot say, but there has never been a war before in which so large a percentage of the wounded recovered. Possibly in the future this proportion may increase, but even as it is many more died in war from disease than from wounds.

◆

The Complimentary Dinner to Surgeon-General J. Jameson, C.B.

WE gave last week a brief report of the proceedings at the complimentary dinner given to Surgeon-General JAMESON, C.B., the late Director-General of the Army Medical Service, at the Hotel Cecil on July 24th. But the occasion was one of unusual interest and of notable character, and warrants us in returning to the subject. Sir WILLIAM CHURCH, who presided, was a member of the South African Hospitals Commission, and had had the fullest opportunity of forming an independent opinion as to the nature and extent of the provisions made for the campaign and of the services rendered by the Army Medical Service. Also he had personally inspected the war hospitals and ascertained for himself their condition, the work they had performed in the field, and the difficulties that had to be overcome. It was fitting, therefore, that he should occupy the position he did when a great gathering of the medical profession assembled "from a desire to do honour to one who had deserved well both of his profession and of his country." Sir WILLIAM CHURCH declared that the war was a perfectly unique war, unprecedented in its character, and that the labours of the then Director-General, who had been like the Israelites called upon to make bricks without straw, had been enormous. The success of the organisation of the hospital service in South Africa was largely due to the rapidity and continuity with which Surgeon-General JAMESON was able to supply the *matériel* and *personnel.* The constancy with which he had stuck to his post and work and the exceedingly able manner in which he had kept up a good relationship between his own corps and their civilian brethren were striking and gratifying features in the late Director-General's administration to which Sir WILLIAM CHURCH called proper attention.

Surgeon-General JAMESON, in replying, was listened to with marked attention and his speech in vindication of the Army Medical Service throughout the South African campaign made a great impression; and it well deserved to do so, for it was dignified and admirable in tone throughout. The story of his department, as he told it, was a most creditable one to all concerned. His speech mainly consisted of well-arranged and lucidly expressed statements of fact of a very pertinent kind. Readers of THE LANCET are pretty well acquainted with the medical history of the war, but Surgeon-General JAMESON from his official position was enabled to speak with a knowledge and precision which others have not done, and to furnish many details and figures which were not hitherto attainable. Everybody has long known that neither the Government nor the military authorities had any real idea of the magnitude and formidable nature of the task which they were undertaking. The force considered sufficient and sent out in the earlier months of the war well-nigh exhausted the available medical establishment; yet troops poured into South Africa until the field force was soon increased threefold. Notwithstanding that the strain on the medical service was enormous it was met. The efforts of the Director-General and his colleagues were ably seconded, as he told his audience, by the nation, the colonies, the civil medical profession, and various volunteer societies, and medical and hospital requirements were provided. As an indication of the work that fell upon the Army Medical Service Surgeon-General JAMESON mentioned that 50,000 invalids had been received from South Africa, India, and the colonies since the beginning of the war, none of whom were transferred to civil hospitals; while there are 21,000 beds equipped at the present time in South Africa without counting the field hospitals. He pointed out that the post of sanitary officer had been abolished against the advice of his department and among many other points he made a remark the significance and importance of which will be at once recognised by all military men, and should not be lost sight of in connexion with the occurrences at Bloemfontein. "After the entry into Bloemfontein, when you hear," said Surgeon-General JAMESON, "that for 10 days there was no officer of the ordnance department present, if there is any blame it should not be put to the medical department." The hospital service has, of course, to depend entirely upon the army supply departments.

Surgeon-General JAMESON's words also threw light upon the relations of himself and his service to the Government and the War Office and military authorities. Are we likely with the best medical officers in the world to have a really good and efficient medical service so long as it can be affirmed that the head of it has not access to the Secretary of State for War, is not a member of the War Office Council over which the Secretary of State presides, or of the Army Board presided over by the Commander-in-chief? Surgeon-General JAMESON said that "it had happened that matters relating to his department had been discussed in his absence and he had not known of the decisions till after considerable delay." If the head of an important service can be treated thus what wonder if recruits to the service are hard to come by. Surgeon-General JAMESON might very truthfully and consistently remark in respect of the present war that the officers of his service did not think that justice had been done to them, and we deeply regret that some army medical officer of rank and administrative experience should not have been nominated as a member of the War Office Committee now sitting.

To one other point we wish to make reference. Sir WILLIAM MAC CORMAC, in proposing the toast of "The Public Medical Services," made the following reference to the omission of the bestowal of titular honour on Surgeon-General JAMESON: "No one," he said, "who had not been in the country itself could know of the difficulties under which the medical department had laboured. They had been blamed for that for which those in other departments were responsible, and it was somewhat strange that the Government had allowed Surgeon-General JAMESON to leave the army without the customary recognition given to every one of his predecessors and without one word of thanks or acknowledgment." The medical profession cannot but feel that this is not the way to treat a very able officer who has rendered conspicuous service to the nation and who was the head of a large and important branch of the army. And not only the medical profession, but the public, know that justice has not been done.

◆

The Results of the British Congress on Tuberculosis.

As with battles so with congresses. There is much smoke or much talk, and only when these have cleared away is the issue apparent. That the Congress, as a congress, was a decided success no one who attended it can doubt. The proceedings were instrumental in eliciting the sympathy and support of a large number of leading men, and the gracious message of His Majesty the KING to the opening ceremony, as well as his reception accorded to the foreign delegates, sufficed to show that the Crown sympathises to the full with the efforts of preventive medicine.

The event of the Congress was undoubtedly the address of Professor KOCH, in which he threw doubt upon the communicability of tuberculosis from animals to man, and it is more than probable that his words will be responsible, as we predicted last week, for the appointment of a third Royal Commission upon Tuberculosis. It must, however, be said that the situation has become markedly modified since that address was delivered. The courteous but trenchant criticism of Lord LISTER and the testimony of Professor BANG, Professor NOCARD, and Professor G. SIMS WOODHEAD, as well as the lucid address by Professor J. MCFADYEAN, have gone far to show that in the opinion of comparative pathologists there are at least other sides to the question. Lord DERBY and Lord SPENCER have as administrators seen the need for caution, while that prince of pathologists, VIRCHOW, has given it to be understood that the last word has not yet been spoken. In this particular aspect, then, the outcome of the Congress cannot be predicted. We may have to wait for the report of a Royal Commission before we are in a position to judge whether Professor KOCH'S statement was justified by the facts or not.

Professor BROUARDEL'S address, although it did not contain a passage of such a sensational character as Professor KOCH'S pronouncement upon bovine tuberculosis, was full of useful information and of encouragement with regard to the utility of preventive measures. The address probably hit the mark when it attributed the decline of pulmonary tuberculosis in this country largely to the better housing of the poor and to the generally improved condition of the labouring classes. There is more to support this thesis than there is that of Professor KOCH to the effect that such decline is due to the erection of hospitals for consumption in this country. We fear that Professor KOCH must have been misinformed as to the number of such institutions and as to the preventive measures which they have, until quite recently, been instrumental in inculcating. Professor BROUARDEL showed what a large amount of work in the direction of popular education as regards the prevention of phthisis is being performed by many nations of the earth, and the valuable part which anti-tuberculous associations and dispensaries are exercising in this direction. With respect to alcoholism Professor BROUARDEL had some very pregnant words to utter, and quoting the words of Sir JOHN SIMON that "the wretched lodging is the purveyor of the public-house," he added "that the public-house is the purveyor of tuberculosis," illustrating his arguments by reference to Dr. TATHAM'S figures. With Chancellors of Exchequers generally Professor BROUARDEL has little sympathy. "They," he remarked, "like to calculate the sum the State get from the duty on alcohol, but they should deduct from it the cost to the community of the family of the ruined drunkard, his degenerate, infirm, scrofulous, and epileptic children who must have shelter." This is sound political economy as well as Christian teaching.

On the last day of the Congress its work was crystallised into a series of resolutions, some of which should have considerable influence in the right direction if adequate and immediate use is made of them. It has to be remembered that several of these resolutions were passed in the State Section where there were present, in addition to a very large number of medical officers of health, Members of Parliament and members of county and district councils. These public workers must see to it that the resolutions which they unanimously passed receive their share of attention when they come, as we take it they will, before the several bodies referred to. The desirability of the notification of pulmonary phthisis attended with tuberculous expectoration was unanimously supported by the State Section; indeed, there were some who wished to make such notification compulsory, and among these were some of our American *confrères* who added so much valuable material to the discussion upon this subject. An expression of opinion such as this cannot fail to have an influence upon the attitude of the Local Government

Board upon this matter. So, too, the expression of opinion that the provision of sanatoria is an indispensable part of the measures necessary for the diminution of consumption will determine the conduct of public bodies who have hitherto been in doubt as to what course they should adopt. The formation of an International Committee to study the behaviour of pulmonary tuberculosis is likely to be attended with useful result, and such a committee might very well take action in respect of steamboats, railway trains, and stations. When we succeed in procuring a uniform system of registration in the several countries we shall have made a great stride towards a proper system of international epidemiology. The other resolutions had concern mainly with the enforcement of home truths, and if these resolutions are made proper use of good results should follow. Among these resolutions there is one which we should like to see thoroughly digested by all local sanitary authorities, not only in this country, but in every other. It was as follows:—

"*That, in the opinion of this Congress, overcrowding, defective ventilation, damp, and general insanitary conditions in the houses of the working classes diminish the chance of curing consumption and aid in predisposing to and spreading the disease.*"

The last resolution of the Congress was proposed by our guest, Professor BROUARDEL, and seconded by Professor CALMETTE of the Pasteur Institute of Lille, and it was to the effect—

> *That while recognising the great importance of sanatoria in combating tuberculosis in every country, the attention of Governments should be directed towards informing charitable and philanthropic individuals and societies of the necessity for anti-tuberculous dispensaries as the best means of checking tuberculous disease amongst the industrial and indigent classes.*

Such dispensaries should, Professor CALMETTE thinks, *precede* and *complete* the foundation of sanatoria, while the enormous amount of good that may be done by them could not have had a more eloquent exponent than Professor CALMETTE.

Looking at the British Congress of Tuberculosis as a whole it seems to us that it has been instrumental in bringing together a large number of workers in the field of preventive medicine both in this country and abroad, and that this act has been attended with a useful exchange of ideas and with a quickening of the public conscience in the matter of State medicine generally and of the prevention of tuberculosis in particular.

Annotations.

"Ne quid nimis."

METROPOLITAN HOSPITAL SUNDAY FUND.

AT a council meeting of the Metropolitan Hospital Sunday Fund, over which the Lord Mayor presided at the Mansion House on July 30th, it was announced that the Committee of Distribution had recommended awards for the present year to 196 institutions. The amount of collections, including interest from the Chancery Division of the High Court, to the present time is £51,000, this sum including £4000 sent by Sir Frederick Cook, M.P., with a request that it might be divided equally between the London Hospital, Guy's Hospital, St. Thomas's Hospital, and St. George's Hospital. That course will be adopted and the money paid to these four hospitals, together with the amount of the award recommended by the committee when confirmed by the council The committee anticipated a further £1500 before the accounts were closed on Oct. 31st. The distribution of £44,534 to 142 hospitals, &c., and to 54 dispensaries was recommended. This year 200 institutions had made applications for grants from the Fund. Of that number it was found necessary to invite the attendance of deputations from the governing bodies of 18. The committee were not able to recommend any awards to two dispensaries and one convalescent home. Deputations from six hospitals and three dispensaries conferred with the committee. The remaining nine replied by letter, leaving the matter in their hands. Explanations modifying the causes of adverse criticism were given in four cases. The serious dissensions between the medical staff and the Board of Management at the National Hospital for the Paralysed and Epileptic, Queen-square, had recently been investigated by a committee of inquiry, the report of which had been followed by the resignation of the secretary-director, and a decision by the governors of the hospital to admit two of the staff to the Board of Management. If that restored harmony between the staff and the board the Distribution Committee would at once report to the council with reference to awards to the National Hospital for the years 1900 and 1901. Five per cent. of the total sum collected—viz., about £2500—was set apart to purchase surgical appliances in monthly proportions during the ensuing year. Mr. George Herring had again most liberally sent a further donation of £10,000 The collections on Hospital Sunday were generally well maintained and showed the confidence that the public had in the Fund. The report was unanimously adopted on the motion of Sir Sydney Waterlow who in the course of his speech asked that a grant to the Royal Eye Hospital might be temporarily withheld pending the investigation of a complaint by the London School Board with regard to the treatment of certain children suffering from ophthalmia. It was also decided that last year's award, together with that for the present year, should be forthwith paid to the National Hospital for the Paralysed and Epileptic.

THE CEREBRAL LOCALISATION OF MELANCHOLIA.

IN a paper which appears in the *Journal of Mental Science* for July Dr. Bernard Hollander makes an attempt to determine the precise area of the brain which is affected in melancholia. Jensen and Tigges had found that the frontal lobes do not show atrophy or loss of weight in melancholia, and hence Dr. Hollander begins by looking for its site in other parts of the brain. Starting from the premise that in melancholia a limited area of the brain is involved because the disease is assumed to be a "morbid condition of the emotional life, affecting an area which is not concerned in intellectual processes," the conclusion is reached that this area is situated in the parietal lobe "particularly the *angular and supra-marginal gyri*." At any rate, the disease is regarded as having its starting-point and as being most intense in these convolutions. It is claimed that in cases of cranial injury involving the parietal eminence and the underlying convolutions—viz., the angular and supra-marginal, as distinguished from other parts of the brain—melancholia is likely to follow. A characteristic case of this was that of a man, aged 28 years who at the age of 17 years fell from a carthorse and sustained an injury of the right parietal *bone (its lower portion)* in the form of a depression from a thrust received by the pole of the cart. He was carried home unconscious. The scalp-wound healed readily but a depression of the skull remained.

Striking mental changes followed. "Patient shunned all association with men, sat for hours brooding in a corner, had daily paroxysms of weeping," and took to bed. He was irritable and would not obey his parents. Dr. Stetter, who was consulted, decided to trephine and the depressed bone was removed. "After the operation the patient returned to social life again and became quite normal."[1] Another case, one of cerebral tumour (cyst) with melancholia was described by Bernhardt[2] as "an extraordinary pathological condition of the brain." The patient was a woman, aged 63 years, who for years had suffered from melancholia with paroxysms of anxiety which increased in intensity so that she made several suicidal attempts. She developed also various hypochondriacal delusions. At the necropsy a cyst was found pressing on the left parietal lobe beneath the dura mater and adherent to it. It produced depression of the greater part of the parietal lobe for about two centimetres below its level. The cyst was of about the size of a hen's egg and filled with serum. There were no entozoic remains in the cyst. Several cases of symmetrical atrophy, or thinning of the parietal bones, are known in association with melancholia. In one of these, reported by Rudolf Bloch, a woman, aged 86 years, was the subject of melancholia and of symmetrical thinnings of the parietal bone, the areas affected by the thinning being 45 millimetres in diameter on the right side and 40 millimetres on the left side. There was a suicidal history in the family. Thirty years previously she had been in an asylum for melancholia and had made several suicidal attempts. The external table and the diploë of the bones were rarefied and thinned out, the bone here being practically reduced to inner table only. In 1854 at a medical meeting in Würzburg, Virchow showed the skull of a man whose chief symptoms were pain, giddiness, and intense melancholy, "and whose facial expression had been observed to be always one of supreme sadness." On both parietal bones, exactly corresponding to the eminences, the bone was so thin as to be perfectly translucent when held against the light. In several cases cited there was a coexistence of "word blindness" with melancholia, especially in lesions of the left side of the brain. Dr. Hollander attempts to give a rational explanation of these facts by stating that the "emotion of fear" is located in the parietal lobe (central part) and that its lesions produce psychical disturbances allied to melancholia.

THE BRITISH DENTAL ASSOCIATION

THE annual general meeting of the British Dental Association will be held in the Examination Hall of the Royal Colleges of Physicians of London and Surgeons of England, Victoria Embankment, from August 2nd to 6th. The proceedings will commence with a reception and entertainment by the Metropolitan Branch of the Association at the Hotel Cecil on Friday, August 2nd, at 8.45 P.M. On August 3rd the first general meeting (members only) will be held at 10.15 A.M. in the theatre of the Examination Hall. At 12.15 P.M. visitors will be admitted and the President's address will be delivered. The second general meeting will be held at 2.30 P.M. From 5 P.M. to 6.30 P.M. there will be a reception by the dean and medical staff of members, ladies, and foreign visitors at the new Dental Hospital, Leicester square. At 8.30 P.M. there will be a reception by the President-elect and Mrs. Hutchinson at the University of London, Imperial Institute road, South Kensington. On Monday, August 5th, the second general meeting will be held at 10 A.M. At 12.30 P.M. Mr. J. Leon Williams, President-elect of the Microscopical Section, will deliver an address on the Use of the Microscope in Dentistry. At 7 P.M. the annual dinner of the Association will be held at the Hot [illegible] Mr. H. G. Howse, President o [illegible] of England, Sir James Crich [illegible] Heath, and Mr. James Smi [illegible] speakers. The fourth general meeting will be held on August 6th. The museum will be open daily from 9 A.M. to 5 P.M.

THE NECESSITY FOR INCREASING THE DOSE OF ANTITOXIN IN CERTAIN CASES OF DIPHTHERIA

AFTER the injection of antitoxin in diphtheria recovery is usually rapid; the general symptoms diminish and the membrane ceases to extend and becomes detached. But in certain cases improvement does not follow and the disease progresses to a fatal termination. This result has been attributed to using antitoxin too late, to associated infections, or to special malignity of the disease. No doubt these are important causes, but there are cases in which the disease progresses because the dose of antitoxin is insufficient and is determined simply by the age of the patient when the gravity of the symptoms necessitates a large dose and its repetition until they regress. At the meeting of the Société Médicale des Hôpitaux of Paris on June 14th, Dr. H. Barbier and Dr. M. F. Lobligeois communicated an important paper on this subject based on cases which they observed in the Hôpital Trousseau in the months of January, February, and March, during an epidemic of diphtheria in Paris of special severity. In some of the cases the symptoms, local and general, did not become worse, but they did not improve. The antitoxin seemed to have simply arrested the progress of the disease. To this form Dr. Barbier and Dr. Lobligeois give the name "prolonged diphtheria." In other cases the symptoms improved and the membrane became detached, then after a variable time the membrane and the toxic symptoms reappeared ("relapsing diphtheria"). The relapses sometimes occurred before the membrane of the first attack had separated, sometimes after it had disappeared, the throat having remained clear for a longer or shorter time. These prolonged and relapsing forms of diphtheria were observed with special frequency in the epidemic referred to and previously in isolated cases. Of 325 cases the membrane persisted in 50 after the third day following the injection. In two the throat was not entirely clear until the twelfth day. The ages of these children varied from 18 months to six and a half years. The dose of antitoxin given on admission varied from 10 to 40 cubic centimetres, usually it was 20 cubic centimetres. The quantity was based on the apparent gravity of the case rather than on the age of the patients. There were 27 cases of "pure diphtheria" to 19 of "associated diphtheria." In most cases a second injection of 10 cubic centimetres given on the second or third day after admission caused the separation of the membrane, sometimes a third and even a fourth injection was necessary. The total quantity of antitoxin given was usually about 40 cubic centimetres. In some cases the dose was increased and from 90 to 140 cubic centimetres were given. In 15 cases the membrane having entirely disappeared, after the injection of antitoxin, which had sometimes been repeated, reappeared. The quantity which had been given varied from 20 to 40 cubic centimetres and in some cases as much as 60, 90, and 140 cubic centimetres were given. The interval between the separation of the membrane and its reappearance varied from one to five days; in one case it was seven days. As a rule an injection of 10 cubic centimetres caused the membrane again to separate in from 24 to 48 hours. In one case the resistance was very great. A child, aged 10 years, for various causes received injections on the first, second, third, fourth, fifth, seventh, and ninth days of the disease, amounting in all to 130 cubic centimetres. Membrane re-formed on the eleventh day, but disappeared under an injection of 10 cubic centimetres. Another indication for increasing the quantity of antitoxin is diphtheritic bronchitis; the dose should be double or treble the ordinary one. Hence the importance of early diagnosis of this complication by careful examination of the chest and of matters expectorated or discharged by the tracheotomy tube. Finally, the persistence of toxic symptoms is an indication to give more antitoxin. Thus a child showed toxic symptoms—prostration and acceleration and feebleness of pulse. The injection was repeated four times and on each occasion there was marked improvement, the prostration diminished, and the pulse became slower and stronger.

THE FOURTEENTH INTERNATIONAL CONGRESS OF MEDICINE, MADRID, 1903.

THE Fourteenth International Congress of Medicine will be held at Madrid from April 23rd to the 30th, 1903, under the patronage of King Alphonso XIII. and the Queen Regent. The subscription is 30 pesetas (equivalent to 24*s*.). Ladies accompanying members will be entitled to the privileges of the members in the reduction of fares on the Spanish railways, &c., on payment of 12 pesetas apiece (or 10*s*.). The National Committee for Great Britain and Ireland remains the same as at the Paris Congress, Sir William MacCormac, Bart., K.C.B, K.C.V.O., being the President. The honorary secretaries are Dr. Percival Horton-Smith of 15, Upper Brook-street, Grosvenor-square, London, W., and Mr. D'Arcy Power, of 10A, Chandos-street, Cavendish-square, London, W.

EPHEMERAL MENTAL DISORDER AND ITS MEDICO-LEGAL ASPECTS.

DR. CHARLES ALDRICH, neurologist to the Cleveland City Hospital, in the May number of the *Philadelphia Medical Journal* deals with the important subject of ephemeral mental disorder (mania transitoria) and refers to its medico-legal aspects. The occurrence of such a condition having a duration of a few hours or a few days—15 to 48 hours according to Kellog—is usually followed by many hours of deep sleep, and owing to its brief duration only symptomatic treatment is possible. The disease usually occurs in young persons and has close affinities with certain forms of psychical epilepsy. Dr. Aldrich records the following two cases. Case 1.—A young woman aged 18 years, with a good family history and free from epileptic attacks or mental aberration, was employed as a domestic servant. She was of steady and religious habits and never addicted to alcohol or narcotics. One morning about 4 o'clock her mistress was aroused by someone beating at her door and loudly calling to her to come out. She opened the door and saw the servant standing in her night-clothes with a Bible under her arm urging her mistress to come with her. She was saying that "the world was about to end and Christ had sent her to save her mistress." The mistress realised that the girl was in a delirium, soothed her, and told her to dress. The girl retired and reappeared dressed, ate a hearty breakfast, meanwhile talking incoherently on religion and the threatened destruction of the world. She then went with a friend to see a procession, keeping her Bible under her arm and maintaining perfect silence for over an hour. Then she said that she felt tired, and on returning home immediately undressed herself and went to bed, sleeping soundly for five hours, after which she awoke "with a dim recollection of the street pageant." She was free from somnambulistic traits and has since the above occurrence never manifested any other symptom of mental aberration. Case 2.—A man aged 40 years, married and in good health, was employed as a workman. He had been always free from mental aberration. "One day while at work ...... he went to his foreman and complained that two of his fellow-workmen were plotting to kill him, and that one of them had a knife concealed in his clothing." The man seemed so sincere and had always been such a sober, industrious, and peaceful workman that the foreman called the other two men to account, who being innocent were perfectly astounded. The patient, however, insisted vehemently on their guilt, and said he had heard their plotting and seen the knife. Of this there was no proof and he was taken home and thence to the Cleveland City Hospital and remained in bed a few days and was discharged. Before his discharge he realised he had been the victim of a delusion and seemed surprised and could assign no cause for it. He had not, says Dr. Aldrich, had a recurrence of any mental symptoms since then or any disturbance of the nature of insanity or of epilepsy. Kellog states that such cases of ephemeral mental disorder are of great judicial interest, "since responsibility cannot exist where consciousness is in abeyance." The treatment was devoted to relief of symptoms and included the administration of hyoscine and morphia as cerebral sedatives, and careful supervision to prevent criminal or suicidal acts during the period of impaired and abnormal consciousness.

UNIVERSITY OF LONDON.

A MEETING of the Faculty of Medicine was held at the University on Friday, July 20th, at 5 P.M. Although the business was specially important less than 30 members were present. An interim report from the Concentration Committee was first presented, but its consideration was postponed until a final report is laid before the members of the faculty early next winter session. Reports were also received from the Boards of Preliminary and Intermediate Medical Studies. The consideration of the reports was also deferred until October, as there was much division of opinion as to whether there should be separate examinations at the Preliminary M.B. Examination in botany and zoology, or whether these subjects should be taken collectively under the general term of biology. The Senate has decided to publish a gazette as a record of matters connected with the University.

THE DIETETIC TREATMENT OF EPILEPSY.

THE dietetic treatment of epilepsy, one of the most hopeful and effective of the more recent therapeutic methods introduced, is dealt with in a recent issue of the *Berliner Klinische Wochenschrift* (June 10th, 1901), by Dr. Rudolf Bálint who contributes an important article based upon observations made by himself at the Clinic of Professor Koranyi in Budapest. The work was undertaken in consequence of the theory advocated by Richet and Toulouse that "salt-starvation" and the administration of alkaline bromides constituted the most effective form of treatment. Dr. Bálint treated 28 epileptic patients who were the subjects of idiopathic epilepsy (*petit mal* and *haut mal*) with a diet from which all chlorides were as far as possible removed, after which a small amount of bromides was added. A number of preliminary trials were made and eventually the following daily diet table was adopted as one satisfying the necessary conditions—viz., from one to one and a half litres of milk, from 40 to 50 grammes of butter, three eggs, and from 300 to 400 grammes of bread and fruit. The bread was specially prepared without common salt and with the addition of three grammes of sodium bromide per loaf. Living on the above diet a patient would consume altogether only about two grammes of sodium chloride per diem, a quantity very much below the average consumption of the salt in every-day diet, while at the same time he would be unconsciously taking about three grammes of sodium bromide daily in his food. The results obtained were highly satisfactory in all the 28 cases. There were a reduction of the epileptic attacks in both frequency and intensity, an improvement as regards mental clearness, and a disappearance of the mental confusion and stupidity so often characteristic of epileptic patients. The general bodily health rapidly rose and "bromism" was never produced. The salient feature was that the sedative action of the bromide was enhanced. Dr. Bálint points out that the treatment is not difficult to carry out and is especially useful and practicable in large institutions where a regulated diet can be enforced. It was a method of treatment attended with no danger and it was especially likely to be useful in epileptic farm colonies and institutions of a like nature.

THE first general meeting of the International Dental Federation will be held in Cambridge on Wednesday, August 7th, the day after the conclusion of the meeting of the British Dental Association in London. Trains for Cambridge leave King's Cross at 9 A.M., Liverpool Street at 9.10 A.M., and St. Pancras at 9 15 A.M. Conferences and committee meetings will occupy the day from 11 A.M. to 5 P.M., when there will be a garden party at Merton Hall, followed by a banquet in Downing College. All members of the British Dental Association and other British dental societies are entitled to attend.

IN consequence of the great pressure on our space, owing to the extensive reports of the British Congress on Tuberculosis and of the annual meeting of the British Medical Association at Cheltenham, we are compelled to hold over the publication of many articles and communications of interest and importance, including our comments on the Interim Report of the Royal Commission on Sewage Disposal.

IMPORTANT VIEWS ON THE RELATIONS BETWEEN HUMAN AND BOVINE TUBERCULOSIS.

AT the present juncture the views of the following three eminent men will be read with interest.

Lord Lister's View.

The following is the full text of Lord Lister's speech made at the second general meeting of the British Congress on Tuberculosis:—

He said that the discourse they had listened to was full of profound interest from the beginning to the end. But what had chiefly riveted their attention had been the startling thesis that bovine tubercle could [illegible] This was a matter of enormous prac- [illegible] were sound it would greatly [illegible] would be a very serious and [illegible] rce for securing purity of milk-supply should be relaxed and it should turn out after all that the conclusion was erroneous. For his own part he thought the evidence adduced by Dr. Koch to show that *human tubercle could not be communicated to bovine animals* very conclusive. At the same time he agreed with him that in a matter of such great importance further inquiry was desirable. But even if that were established it would by no means necessarily follow that bovine tubercle could not be communicated to man. He took in illustration the case of variola. Attempts to inoculate human small-pox into the calf had been so very rarely successful that eminent pathologists had concluded *that small pox and cow-pox were two entirely different* diseases. We now knew that this was an entire mistake; that cow-pox was small pox modified by passing through the cow. He referred to some very instructive experiments by Dr. Monckton Copeman, who entirely failed to inoculate human small-pox into the calf but invariably succeeded in inoculating it into the monkey, and was as invariably successful when he intro- [illegible]

tudes of tubercle bacilli swallowed by them in milk. Even if it were [illegible]

argument fell to the ground. As regarded the experiments which Koch had referred to of inoculating bovine animals with material from the glands of children affected with tabes mesenterica, the result being negative, these experiments had been but few; and even were they more numerous, they would not, to his mind, be quite conclusive. It might be that tubercle from milk in the intestines might be so modified by passing through the human subject that the bacilli in the mesenteric glands, though derived from a bovine animal, might be no longer those of true bovine tubercle but bacilli having the characters of human tubercle little disposed to develop in cattle. The Congress would probably require a more searching inquiry into the subject before accepting this doctrine of the immunity of man to bovine tubercle.

In the evening issue of the *Berliner Lokal Anzeiger* of Friday, July 26th, there appeared a report of interviews which a representative of that journal had had with Professor Virchow and Professor Heubner on the receipt in Berlin of the particulars of Professor Koch's pronouncement as to the difference between bovine and human tuberculosis. The following is a free translation of their remarks.

Professor Heubner's View.

Professor Heubner, who was first to be interviewed, said:—

If Koch in his address in London expressed the opinion that heredi- [illegible]

Professor Virchow's View.

Professor Virchow expressed himself as follows:—

I have for many years opposed the theoretical belief in hereditary transmission of tuberculosis in [illegible] with Koch. In a discourse whi [illegible] Berliner Medicinische Gesellsc [illegible] standpoint on this matter, for [illegible] which Professor Koch enunciate [illegible] I would point out that Koch [illegible] *investigations, disregarded* t [illegible] indebted to the Copenhagen school. In order to ascertain what was best that could be done for the health of the people, and particularly what foods and liquids they should avoid, the Danish Government appointed a Commission which, it appears, consisted mainly of medical officers and was known as the Council of Health. Among the many questions which the council paid careful attention to was, of course, that of bovine tuberculosis, and for the purpose *of settling the question* in a scientific manner the most minute investigations were made and the results of these investigations form practically the basis upon which all subsequent public health acts are founded. I may refer to our enactments concerning quarantine, for instance, in illustration of the extent of our indebtedness to the scientific work of the Copenhagen school. The conclusions arrived at by the Danish scientists are very different in character from those of Professor Koch. The question is anything but settled.

EDINBURGH UNIVERSITY.—At the summer graduation ceremonial of Edinburgh University, which took place on July 27th in the M'Ewan Hall, the degree of Doctor of Medicine was conferred on 61 candidates, six of whom were awarded gold medals for their theses. The gold medallists were James Martin Beattie, Thomas Hastie Bryce, Evan John Howat Fraser, Alfred Charles Sandstein, Sutherland Simpson, and Donald Bremner Waters. The Ettles Scholarship was awarded to Caleb Williams Saleeby. The degrees of M.B., C.M. was conferred on 11 candidates and the degree of M.B., Ch.B. on 147. The address to the graduates was delivered by Professor John Wyllie.

THE BRITISH CONGRESS ON TUBERCULOSIS.

His Majesty the King received at Marlborough House on Thursday afternoon, July 25th, the foreign delegates to the Congress. His Majesty shook hands with each delegate in turn and then made the following speech :—

"Gentlemen,—Let me express to you the great pleasure and satisfaction it has given me to ask you to come here to-day, and I only regret that you should have arrived during such a severe thunderstorm.

It has been a source of great concern to me that owing to circumstances over which I had no control I was prevented from presiding at the opening of your important Congress and attending its meetings, but I can assure you that though not present I take the deepest interest in its proceedings and that I follow, through the medium of the daily press, with much interest the papers which are read and the discussions on the subject.

There is no more terrible disease than that known as consumption, and I only hope and trust that you may be the means of minimising its evil effects and thereby receive the gratitude of the whole world.

There is still one other terrible disease which has up to now baffled the scientific and medical men of the world, and that is cancer.

God grant that before long you may be able to find a cure for it or check its course. I think that to him who makes the discovery a statue should be erected in all the capitals of the world

In taking leave of you I trust that your stay in London, and in England, has been an enjoyable one, and that you will one and all carry away pleasant recollections of your visit to my country."

The Fourth General Meeting.

The fourth general meeting of the Congress was held in the Queen's Hall on July 25th, at 3 P.M., to hear an address from Professor **J. McFadyean**, M.B., M.R.C.V.S., on Tubercle Bacilli in Cow's Milk as a possible Source of Tuberculous Disease in Man. This will be found in full on p. 268. Much interest was taken in the delivery of this paper, as it was an open secret that it would be a direct answer to the views of Professor Koch.

The chair was taken at the meeting by Lord **Spencer** who, before he called upon Professor McFadyean to deliver the address, pointed out that though he himself was a layman and did not imagine he could give an opinion regarding the scientific view of the matter, still for the pronouncements of scientific men to be of use they must have the support of public opinion. In his judgment he still considered that the public should be protected from the sale of milk from diseased sources. The agriculturists had a great deal of risk in this matter and though he had great sympathy with the views expressed by Mr. Chaplin he felt confident that the agricultural world would give its support to the regulations required to prevent infection from tuberculosis.

Sir **James Crichton Browne** informed the meeting that the official delegate of the State of Wisconsin (Dr. Brown) had received an answer from his Government to a telegram which he had despatched giving Professor Koch's statements and the answer was that they would "begin experiments to-morrow." He considered that further consideration was necessary before accepting Professor Koch's views and that the Government should undertake an investigation.

The next two speakers were Professor **Nocard** and Professor **D. J. Hamilton** (Aberdeen), who declared that bovine tuberculosis was a source of danger to the human race.

Dr. **M. P. Ravenel** (Philadelphia) instanced several cases where bovine tuberculosis had occurred in man from accidental infection

Professor **E. M. Crookshank** said that in consequence of the publication of Professor Koch's opinion the measures that had been devised for the safety of the public might be paralysed. At that Congress a great variety of interests were represented and they would all agree that free and open discussion was the only way to secure the truth. His own opinion was that Professor Koch was quite wrong in consequence of a too precipitate generalisation from the facts before him. He protested against Professor Koch's view that no measures should be undertaken for the prevention of infection of man from bovine tuberculosis.

The proceedings closed with a vote of thanks to Professor McFadyean.

The Final General Meeting.

Under the presidency of Lord **Derby** the fifth (and final) general meeting of the Congress was held at Queen's Hall on July 26th.

Lord **Derby** said they had reached the last stage of their official proceedings at the Congress and it became their duty to submit certain resolutions which had been arrived at in the sections. He thought the Congress had achieved a success which would render it one to be remembered among the history of similar congresses in the world.

Mr. **Malcolm Morris** proposed :—

> That tuberculous sputum is the main agent for the conveyance of the virus of tuberculosis from man to man and that indiscriminate spitting should therefore be suppressed.

He said it was not a particularly pleasant subject, but it was the key to the whole question, and they must come boldly to the point and carry the motion.

Mr. **Harold Swithinbank** seconded the resolution and said that it was time that they prevented the indiscriminate distribution of tuberculous poison in sputum in the streets.

The motion was put and carried.

Professor **G. Sims Woodhead** proposed :—

> That it is the opinion of this Congress that all public hospitals and dispensaries should present every out-patient suffering from phthisis with a leaflet containing instructions with regard to the prevention of consumption and should supply and insist on the proper use of a pocket spittoon.

Sir **William Broadbent**, in seconding, said that a measure of that kind was of the first necessity to prevent the out-patients' departments becoming centres of infection.

The motion was carried.

Dr. **J. Niven** (Manchester) proposed :—

> That the voluntary notification of cases of phthisis attended with [illegible] the increased preventive action which [illegible] of [illegible] in all districts in which efficient [illegible] possible to adopt the consequential measures.

He said that in dealing with such a large subject as the notification of phthisis he could not do wrong in saying that the way in that practical measure had been shown to them by their American cousins in New York where they had carried on in ever-increasing efficiency a large measure of notification of phthisis.

Professor **T. Clifford Allbutt** (Cambridge), in seconding the motion, which was duly carried, said that it was possible by the means proposed to enable working men to attend to their work while under treatment.

Sir **John Burdon Sanderson** (Oxford) proposed :—

> That the provision of sanatoria is an indispensable part of the measures necessary for the diminution of tuberculosis.

He urged that sanatoria were of great value to all classes of the community, but especially for the poor workman whose earnings were only sufficient to cover his expenses, but who was too poor to make proper provision against the great calamity of sickness.

Sir **Richard Douglas Powell**, in seconding the motion, which was carried, said it was quite unnecessary for him to add any words to the eloquent remarks of the proposer.

Sir **Herbert Maxwell** proposed :—

> That in the opinion of this Congress and in the light of the work that has been presented at its sittings medical officers of health should continue to use all the powers at their disposal and relax no effort to prevent the spread of tuberculosis by milk and meat.

He said that those who had heard the magnificent oration of Professor Koch on the one hand, and of Professor McFadyean on the other hand, would perceive that, like other questions, it had two sides.

Lord **Spencer** seconded the motion, which was carried, and said that he would like to urge on all those who have to act in that matter the advisability of judicious methods of administration with a certain amount of elasticity and a great deal of good sense in their regulations.

Dr. **G. A. Heron** moved, and Mr. **F. J. Lloyd** seconded, the following :—

> That in view of the doubts thrown on the identity of human and bovine tuberculosis it is expedient that the Government be approached and requested to institute an immediate inquiry into this question, which is of vital importance to the public health and of great consequence to the agricultural industry.

Dr. R. FARQUHARSON, M.P., said that though they could not ignore such an authority as Professor Koch he thought they had done well to keep to the *status quo ante.*

The motion was then put to the meeting and carried unanimously.

Sir JAMES CRICHTON BROWNE moved that—

> The educational work of the great national societies for the prevention of tuberculosis is deserving of every encouragement and support. It is through their agency that a rational public opinion may be formed, the duties of public health officers made easier of performance and such local and State legislation as may be requisite called into existence.

He said that the work of the Congress could be summed up in the one word "enlightenment"

Dr. ALFRED HILLIER seconded the motion which was put and carried.

Sir WILLIAM BROADBENT moved the following:—

> [illegible] of prevention This Congress is further of opinion that such a [illegible] be elected by the great [illegible] of tuberculosis and also [illegible] nents It is further of [illegible] great national societies [illegible] s should be invited to coöperate

He said [illegible] work in exciting [illegible]

Profes[illegible] aid that the work [illegible] struggle against tuberculosis

The motion was carried.

Professor CROOKSHANK proposed:—

> [illegible] predisposing to and spreading the disease.

He said that they must not confine their attention to the tubercle bacillus alone but must consider the other factors in the production of tuberculosis

Dr. C THEODORE WILLIAMS seconded the motion and explained how the depressing conditions under which they lived caused the milliner, the tailor, the printer, and others to become liable to the attacks of the disease.

The motion was carried.

Professor BROUARDEL submitted the following motion which was seconded by Professor CALMETTE and duly carried:—

> That while recognising th[illegible] bating tuberculosis in ever[illegible] should be directed towards [illegible] individuals and societies of [illegible] saries as the best means of [illegible] industrial and indigent classes

The last motion was proposed by Professor ROBIN and seconded by Sir WILLIAM BROADBENT and carried:—

> That the following question be submitted to the consideration of the next Congress:—The constitutional conditions of the individual which predispose to tuberculosis and the means whereby they can be modified

The CHAIRMAN, after replying to a question from Mr. BOWEN-JONES (Shrewsbury), who spoke from the back of the hall and to whom he explained that the resolutions of the Veterinary Section were not submitted because they were unsuitable for discussion at that particular meeting, congratulated the members of the Congress on the successful termination of their labours

---

THE SECTIONS.

SECTION I.

STATE AND MUNICIPAL.

THURSDAY, JULY 25TH.

DIVISION IV., THE INTERNATIONAL ASPECTS OF TUBERCULOSIS.

A general discussion upon this subject was opened by Dr. ALFRED HILLIER (London). Having dealt with the conditions essential to the establishment of tuberculosis in man Dr. Hillier proceeded to discuss the measures which had been taken by science to check the introduction of the bacillus. Could they doubt that protection from the indiscriminate distribution of sputum would result in tuberculosis becoming more completely under control than small-pox? He then considered what was being done in the civilised States of Europe and America to check the disease and then in general terms mentioned what they were called upon most urgently to do. The movement for [illegible] any was ahead of that in [illegible] for all classes The Uni[illegible] way in practical downright measures of prevention. To France must be accorded the honour of having done more for the education of public opinion [illegible] It was worth noting that [illegible] making notification of tub[illegible] compulsory. Denmark als[illegible] struggle against the disease. He suggested the formation of a committee in which all civilised countries should be represented and its work should be to formulate the principles on which all were agreed and to define the broad line of action which should be taken. Legislation could never terminate by itself many of the abuses associated with the spread of tuberculosis, but if fortified by public opinion it could and would do so

Dr. F. MONTIZAMBERT (Canada), *Director-General of Public Health, Ottawa, Canada, Delegate of the Canadian Government,* read some

Notes on Tuberculosis in the Dominion of Canada.

He said: Tuberculosis in the Dominion of Canada, as elsewhere, has heretofore levied a heavy tax upon the well-being and the lives of the people. Some 8000 deaths per annum in Canada are attributed to this disease. Some of these are, of course, amongst native-born Canadians; others are amongst those who have brought the seeds of the disease with them from other countries Here, as elsewhere, the knowledge of the true nature of the disease and of the methods of its spread has advanced *pari passu* with the advances of medical science With this extension of knowledge in the medical profession have come also wiser counsels to patients and their friends and to the public This was until recently only the action of boards of health, of medical societies, of individuals, and of comparatively small local associations. This year, however, Lord Minto, the Governor-General of Canada, has organised a national movement for the prevention and cure of this disease—the Canadian Association for the Prevention of Tuberculosis Of this association his Excellency is the honorary president. The first meetings were held in Ottawa in February last and the work of this general national movement was begun—the work of endeavouring to rouse to a sense of their danger the mass of the people, whilst at the same time a knowledge of the possibility of prevention and cure is brought home to their [illegible] nd they are thus both encouraged and urged to [illegible] practical measures necessary to attain the great [illegible] view—the limitation, if not, indeed, the extinction, of this preventable disease Already some of the municipalities are moving in the matter. If there be anything in climatic influences in the prevention and cure of tuberculosis Canada offers a wide field for choice She stretches from ocean to ocean and her vast inland tablelands and mountain ranges offer all the elements of dryness, altitude, and clearness of atmosphere, with absence of strong penetrating winds, that may be desired And this with a variety of grandeur of scenery and full opportunities for outdoor sports, hunting, fishing, &c., for those who seek them; and for all the pleasant summer weather and the dry and invigorating cold in winter render life and rest out of doors a possibility and a benefit at all seasons of the year by night as well as by day

Professor ROBINSON (America) referred to the measures which had been taken in the State of Maine to combat disease and which were attended with some success. The first [illegible] cation of the people in reference [illegible] This great work of education [illegible] e result was really remarkable. [illegible] n a lessening of the mortality in seven years [illegible] rate due to phthisis of more than one-fourth. Sanatoria were being built by voluntary contributions.

Dr VAN RYN (Belgium). General Secretary of the Belgium National League against Tuberculosis, having passed in review the Present Position of the Crusade against Human Tuberculosis in various countries.

Dr HOLGER RÖRDAM (Denmark), *Chief Physician of the First Class of the Denmark Naval Marine,* described the

Measures taken against Tuberculosis in Denmark.

Compared, he said, with many other countries in Europe, Denmark remained for a long while behindhand in the struggle against tuberculosis, but during the last few years the inhabitants had taken up the matter with considerable energy. The oldest hospital for tuberculous patients was situated in the peninsula Refsnaes. It was founded in 1874. It was arranged at first for 100 patients; later, it was increased to accommodate 130, without reckoning 12 beds in the establishment for patients suffering from epidemic complaints and 16 beds in the ward for ordinary diseases. The hospital only admitted scrofulous children. The construction of the whole establishment had cost about 500,000 francs, and the fitting of it up about 60,000 francs. The money for the construction and the working of the hospital had been furnished up to a certain point by private benefaction, but the State and the municipalities had also contributed their quota. The municipality of Copenhagen possessed, in addition, a small hospital for scrofulous patients at Snogebeck, in the island of Bornholm, where 70 children were treated last year, this costing 10,000 francs. The Society for Children's Hospitals in Copenhagen and its Suburbs, which was formed 10 years ago, now possessed an establishment at Hellebock, at which 197 children were treated in 1899. The aim of the society was to found a sufficient number of small hospitals situated on the sea-coast, where weakly, and above all scrofulous, children should be admitted without pay. The Finsen Institute was founded at the initiative of Professor Niels Rigberg Finsen, in 1896, for the purpose of making experiments, and of contributing to the progress of research on the effect of light on living organisms; above all, with the intention of utilising the rays to the benefit of practical medicine. The institute, the administration of which was under the presidency of M. Blagemann, manufacturer and municipal councillor, had received numerous private donations, and by the Financial Act of 1900 it had been voted a sum of 350,000 francs as a loan without interest. The institute was established at Rosenvaenget in Copenhagen. The number of lupus patients who had been cured was very considerable. A large hospital for scrofulous children at Juilsmind was in course of construction; the treasury had supplied 80,000 francs, and Prince Carolath had made a present of an excellent site. As a hospital for phthisis properly so called there existed but one at the present time, situated on the fjord of Vejle à Fakkegrav; it was opened on March 1st, 1900, with room for 92 patients. The hospital was founded under the name of "Hospital for Consumptives" by a society the aim of which was philanthropic. The dividend on shares being limited to 4 per cent. the subsequent profit would be employed to lessen the payments of those in straitened circumstances. Danish physicians had contributed a sum of 60,000 francs, and private persons 300,000 francs. The treasury had given 150,000 francs, and for non-paying rooms a donation of 30,000 francs had been received. The sanatorium was situated on the fjord of Vejle and possessed considerable forest land. All expenses included, the hospital had cost about 1,100,000 francs—that was to say, 12,000 francs per bed. During the 10 months March to December, 1900, 206 patients had been treated at the sanatorium. The payment for Danish subjects per day was from 10 to 11 francs for a separate room and from eight to 10 francs for a common room. To foreigners the highest fee was five francs daily. The hospital was under the management of Dr. Sangmann, the head of the staff. The municipality of Copenhagen were having a sanatorium for consumptives constructed in the forest of Boscrup, near Roskilde. Up to the present day this was all that had been done in Denmark in the way of constructing sanatoria. In 1898 the Association of Danish Physicians presented a petition, supported by an address signed by 200,000 of the population, to the Government and to the National Assembly having as an object the construction of sanatoria for consumptives as well as the founding of hospital establishments and the supply of aid to the families of patients. For this purpose they demanded the nomination of a commission, and the relief organisations in cases of sickness had in 1900 presented an address, supported by 250,000 signatures, requesting the establishment of three State sanatoria. On grounds of expense the Government had not ventured to include this item in their Budget. On Jan. 19th, 1901, at the instigation of the speaker and of M. Karl Loventsen, doctor of medicine and editor of the Danish journal of hygiene, the National League to Combat Tuberculosis was founded and was received with great enthusiasm on the part of political personages of the highest distinction, physicians, civil servants, and financiers. The minimum annual subscription was three francs, and the league now numbered 10,000 members, this giving an annual income of 100,000 francs. The aims of the league were the establishment of popular sanatoria for the poor, public lectures to enlighten people as to the nature of tuberculosis, and the giving relief to the families of patients. As to precautions established by law against tuberculosis, there were very few of them in Denmark. Gratuitous disinfection after cases of death due to tuberculosis was enjoined and apprentices before being admitted to manufactories were bound to show a medical certificate declaring that they were in good health, while by a new law relating to labour in factories decreed last year some regulations as to cleanliness in these establishments had been enacted. But that was all that had been done on the part of the Legislature. The Sanitary Commission of Copenhagen had enacted that practising physicians might have sputum examined for tubercle bacilli free of charge in doubtful cases of phthisis. Receptacles required for the receipt and transmission of the sputum were to be had from all the pharmaceutical chemists in the city, and were delivered up for examination at the laboratory of the Sanitary Commission, 12, Norrevaldgada. The laboratories, in their turn, would send a written report on the result of the analysis to the physician concerned at the earliest possible moment. In almost all the towns of Denmark control over meat-supply was established, but it was solely an affair of the town whether it elected to put such control in force. In regard to tuberculosis among animals, thanks to the efforts of Professor B. Bang, Denmark occupied a position among the most advanced nations. In almost all the principal towns there were private associations which were charged with controlling the wholesomeness and the price of milk. All things considered, it appeared that Denmark had not progressed badly in the battle with tuberculosis. The mortality caused by tuberculosis was diminishing in a marked manner.

M. DA SILVA ARNADO, as a representative of Portugal, spoke of the anti-tuberculous movement in that country.

Control of Milk Supplies.

Professor **S. DELÉPINE** (Manchester) was set down in the programme to open a discussion upon the Exact Statistics of the Tuberculin Test. Those who know the enormous amount of accurate and expensive work that has been done in Manchester by Professor Delépine and his colleagues will regret that this communication should have been crowded out.

Professor **DELÉPINE** proposed, and Dr. **J. ROBERTSON** (Sheffield) seconded, a motion against accepting Professor Koch's conclusions and proposing that further inquiry should be made into the subject and that the matter should be brought before the Local Government Board and the Board of Agriculture. This motion, which was carried unanimously, was introduced by Professor Delépine in the following manner:—

I feel it necessary to allude to the statements of Professor Koch two days ago regarding the relations of human and bovine tuberculosis. On reading the newspapers yesterday I was much pained to find that Professor Koch had made a statement which would undoubtedly deal a great blow to the work of those who were responsible for the public health of this country. Such a blow seemed to me unnecessary and unjustifiable under the circumstances. It is hard to disagree with the discoverer of the tubercle bacillus and of tuberculin, and the task is as ungrateful as it is hard. I feel, however, that Professor Koch, before making statements challenging the accuracy of facts which, to all competent observers, are well-proved facts, should have given us the means of finding how it was that we had been deceived by scientific observation which appeared to be reliable. He should have opened our eyes and shown us that what seemed facts, and which I still believe to be facts, were not facts at all, but erroneous interpretations. I think that Professor Koch's great authority and high position do not justify his disturbing public opinion by expressing views unsupported by evidence; on the contrary, his position should make him more careful than any other man, for his statements are bound to have a considerable influence upon those who have no means of testing his views by their own experience. I have said that I still believe in the evidence proving the unity of human and bovine tuberculosis. The evidence is, I believe, very clear. 1. We have cases of veterinary surgeons becoming infected with tuberculosis as a result of wounds received during the necropsy of tuberculous cattle. Several such cases are fully recorded as authentic and their existence cannot be denied. We have much post-mortem evidence to support the idea that bovine tuberculosis can produce tuberculosis in children by ingestion. 2. We have evidence that human tuberculosis can be communicated to most of our domesticated animals. 3. In certain animals used as test animals—e.g., the guinea-pig—inoculation with products from human and bovine tuberculous subjects produces a disease which has all the chief characteristics of tuberculosis in either man or cattle. This tuberculosis can be almost invariably obtained and follows a very definite course, as I have been able to satisfy myself by some 3000 personal experiments. 4. Tuberculin which contains specific chemical products generated by the tubercle bacilli can be obtained from tubercle bacilli of various origins, and tuberculous cattle react to tuberculin prepared with these various bacilli. Before all these facts can be explained I think that it will be impossible for us to admit the view that human and bovine tuberculosis are essentially different, as was formerly believed before the experiments of Villemin. I think, therefore, that the authorities will do well not to relax their efforts and should continue to combat bovine tuberculosis as strenuously as ever. I will therefore move the proposition, which has the support of your President, Sir Herbert Maxwell, and of Dr. J. Niven, Dr. A. Newsholme, and Dr. H. T. Bulstrode.

A proposition was then read against accepting Professor Koch's conclusions and passed unanimously. Slightly shortened, it was passed unanimously at the fourth general meeting on Friday, July 26th.

Next came Mr. J. S LLOYD, whose paper on the Veterinary Work in Connexion with the Milk Clauses in Manchester will be found on p. 274.

Dr. P. BOODBYER (Nottingham) proposed, and Mr. JAMES DICK (Glasgow) seconded, a motion urging that the Local Government Board should issue a circular or memorandum with regard to this question, which was carried unanimously.

Dr. MALM, a delegate of the Norwegian Government, then submitted the following aphorisms with regard to the use and value of tuberculin:—1. The tuberculin *employed as* diagnostic should be a tuberculin produced on the same principles as that of Professor Koch in 1890. Its strength should be uniform and it should be of such toxic strength as to kill with certainty guinea-pigs infected from six to eight weeks previously within eight hours in doses of from 20 to 30 centigrammes subcutaneously. 2. Such a tuberculin produces unfailingly in tuberculous animals a febrile reaction of a distinct type. It is recommended that large doses should be *given, even to young animals*; there is no danger or inconvenience in always employing doses of from half a gramme to one gramme. 3 Tuberculin may at times also produce fever in non-tuberculous animals, but this fever is not typical and does not attain such a degree as in tuberculous cases. 4. If typical tuberculous reaction appears in an apparently healthy animal, and on dissection nothing tuberculous is found, it is the fault of the dissector. 5 To determine with certainty whether reaction exists or not it is necessary to take the temperature from the sixth to the twentieth hour, after injecting hourly or at least every second hour. 6. The fact that tuberculin in a few isolated instances produces fever in non-tuberculous animals is of no importance when the question is its usefulness as a means to eradicate tuberculosis, and in this respect it is decisive, as tuberculin invariably causes reaction in tuberculous animals. 7. The foregoing refers to animals treated for the *first* time. Most animals become more or less accustomed to the tuberculin, but this is uncertain and unreliable and can be overcome by the use of an increased dose or a tuberculin of greater toxic strength. 8. The practical combating of tuberculosis concerns administrative, economical, and social spheres and the answer must vary in different countries according to the prevalence of the disease and its extent, the system of farming and cattle-trade, and the pecuniary means available.

Mr. DROOP RICHMOND, F I C. (London), *read a paper on*

The Relative Advantages in the Prevention of Tuberculosis of the Use of Sterilised Milk, Pasteurised Milk, and Milk obtained from Herds free from Tuberculosis,

of which the following is an abstract:—*Efficiency of the three methods.*—All the methods, if properly applied, would yield milk free from tuberculous infection. *Chemical changes on heating milk.*—Changes take place in milk at the following temperatures. At about 60° C.—Formation of skin on the surface, if exposed to air. At about 70° C.—Conversion of the albumin into its less soluble form, and alteration of taste of the milk. At about 80° C.—Destruction of the substance in milk which reacts with the phenylenediamines and hydrogen peroxide (? *enzyme, and substances* conferring immunity from Barlow's disease). At higher temperatures, especially at 100° C. or above.—Caramelisation of the sugar, fusion of the fat globules, and marked alteration of taste; possibly slight change in the proteids or their combinations with salt manifested by the reactions towards rennet and litmus being modified. *Discussion of commercial methods.*—(*a*) Pasteurisation.—This term was applied to heating milk to any temperature between, say, *50° to nearly 100° C.*, for a short period (not exceeding 20 minutes). The work at the Wisconsin station had shown that it was important to keep the milk agitated. Pasteurisation in bottles or in the ingenious apparatus of Hewlett was not always to be depended on. The Lawrence pasteuriser did not provide for a sufficient length of heating to be absolutely safe. Pasteurisers consisting of jacketed pans with a revolving stirrer were the most efficacious and convenient. They could be so arranged that the milk ran through continuously and could be kept at the required temperature for any length of time. Pasteurised milk was scarcely distinguishable in taste from ordinary milk; the cream did not rise so rapidly if the milk had been heated over 70° C. (*b*) Sterilisation.—As the object of sterilisation was to kill all micro-organisms milk must be protected after sterilisation; this was secured by sterilising in vessels which were closed immediately after sterilisation was complete. Commercially intermittent sterilisation was not practicable, as the cost of handling the vessels several times was great and the cream had a tendency to fuse more and more at each successive heating. Two sterilisations were the utmost practicable; temperatures of 100° C. or over might be used and the length of heating depended on the temperature. Higher temperatures were more effective than lower ones. Sterilised milk was distinctly changed in taste and was deprived of anti-scorbutic properties; also, unless efficiently sterilised, *highly resistant spores* might be left undestroyed and as infantile diarrhœa was due to this class of organisms the milk might be dangerous. (*c*) Protection of milk by veterinary inspection.—The whole of the cows from which the Aylesbury Dairy Company's supply was derived were individually examined and periodically inspected by qualified veterinary surgeons with regard to the existence of any condition likely to render the milk harmful, and especially with regard to evidence of tuberculous disease Every *animal* showing the *slightest* suspicion of tuberculosis was not only submitted to the tuberculin test and condemned if found to react, but its milk was also microscopically examined. The herds were placed under the personal supervision of local veterinary surgeons, who, in the same manner as the local medical officers had done for many years past, visited the farms frequently and regularly.

FRIDAY, JULY 26TH.

DIVISION V., THE PROVISION OF SANATORIA.

Sir JAMES CRICHTON BROWNE, F.R.S., gave an address on the Best Means of Promoting the Erection of Sanatoria for Phthisical Patients in which (1) the curable may have the best chance of recovery afforded to them; and (2) the incurable, whilst ceasing to be a source of danger to the community, may have their lives prolonged and receive the comfort necessary to their condition. He showed that the pathological and clinical evidence of the curability of consumption was convincing. The invaded lung was largely able to take care of itself, but stubborn though the resistance was to the ravages of the disease, yet the bodily powers required some reinforcement from without, and the medical world had come to the conclusion that this extraneous help was best afforded by the establishment of sanatoria He did not claim finality, for the time might come when some sovereign remedy might be discovered to put an end to this disease. It was too early to form any numerical estimates of the good results of the sanatorium treatment. He concluded by dividing the patients into three classes: (1) the affluent, (2) the competent, and (3) the indigent, and laid down the lines of treatment for each class. The affluent class on the whole were best treated at home with the proper care which their circumstances allowed them, but the two latter classes were best treated at sanatoria. He believed that sanatoria once built and started would be self-supporting, and the cost to the patient would be such as the means of his class would [illegible]

Mr. E. W. BRABROOK, C.B., Chief Registrar of Friendly Societies of Great Britain and delegate of the Royal Statistical Society to the Congress, spoke next. If the liability of friendly societies, he said, to claims for sickness and or would be diminished by the establishment of sanatoria it would be to the interest of such societies to contribute to a certain extent towards their construction and maintenance. This the societies had the legal power to do, under certain conditions, by Sections 22 and 37 of the Friendly Societies Act, 1896. The extent of their interest was not so great as might be supposed. The liability of their members to phthisis was not so great as was that of the general population. Again, early mortality relieved the society from its liability to future sick pay. Where children were admitted members they were required to pass a second medical examination at the age of 16 or 18 years. The ages of 3,699,804 members of friendly societies were recorded, 7 per cent. being under 16 years; 7 per cent. between 16 and 20 years; 67½ per cent between 20 and 50 years; 14½ per cent. between 50 and 65 years; and 4 per cent. over 65 years. Trade unions might also, under certain conditions, join in the establishment or maintenance of a medical society. In four of the larger of these bodies the deaths from phthisis were from 10 to 13 per cent. of the total number of deaths, and the average age at death from phthisis varied from 35½ to 39½ years and from all causes from 43 to 52 years. The conclusion at which he arrived was that while theoretically the question put must be answered in the affirmative the financial interest of the societies was too small to allow of its being reduced into practice to any material extent.

Sir JOHN BURDON SANDERSON then made certain propositions in respect of Sanatoria for Working Men and Women. In Germany, he said, more than 50 sanatoria, affording accommodation for about 4000 working men, were in operation. The success of the experiment had been such as to afford ground for believing that by the timely admission of the consumptive workman into a sanatorium his life might be prolonged. In Germany the funds required for maintaining workmen's sanatoria were chiefly derived from the system of compulsory insurance against illness which existed in that country. It might be assumed that no such system could be established in England. It must, at the same time, be admitted that the expenditure required for the maintenance of the working man when incapacitated by sickness must be principally derived from his earnings; in other words, some form of voluntary insurance against disease must be regarded as the best substitute for the compulsory system as it existed in Germany. A system of sanatoria supported by voluntary insurance (as, for example, by the industrial insurance societies which existed in this country) could not be as efficient as a means of diminishing the frequency or spread of pulmonary tuberculosis as a system dependent on compulsory insurance. As regarded the individual contributor it would no doubt be more advantageous, because its benefits would not be extended to the inferior class of workmen who were most liable to phthisis. But for the same reasons it would be less advantageous to the health of the community, for in this relation the degree of advantage arising from the prompt removal of an infected person from his dwelling and its insanitary surroundings was proportional to his poverty. A system which would provide for the well-to-do workman, excluding the toiler whose earnings were not more than sufficient for bare maintenance, would be unsatisfactory unless it were largely supplemented by funds derived from other sources.

Herr BIELEFELDT (Berlin) gave a description of the battle against consumption as carried on in Germany with the aid of the German workmen's insurance. He expressed the conviction after several years' experience that an effective battle against consumption among the working classes would have been impossible without the workmen's insurance in Germany, with its powerful pecuniary resources and its legal and social regulations.

Mr. FREDERICK L. HOFFMAN, statistician to the Prudential Insurance Company of America made a communication to the section, by invitation, upon Industrial Insurance in Relation to the Prevention of Tuberculosis. By numerous interesting charts he showed that the deaths from tuberculosis in the United States of America amounted to about 200,000, but that the death-rate was gradually, if slowly, coming down. The Prudential Insurance Company of America, while recognising that the interests of industrial insurance companies in the prevention of tuberculosis were coincident in America with those of the population at large—for in the United States four-fifths of the population were insured somewhat on the industrial plan—did not consider that it would be expedient for them or any similar corporation to erect and to maintain sanatoria for the treatment of their policy-holders. If they were to entertain such a project they would at once be confronted with requests to make equal provision for other sufferers and even for the injured from accidents, and if they acceded to such requests the interests of their healthy policy-holders would be sacrificed to those of the sick.

Mr. Hoffman was followed by Dr. T. E. HAYWARD, medical officer of health of Haydock, who read a statistical paper on Mortality from Phthisis.

Lieutenant-Colonel MONTEFIORE, secretary to the Medical and Convalescent Committee of the Charity Organisation Society, read a paper on the Provision of Sanatoria, with Reference to Some of the Difficulties which Arise in Assisting the Phthisical Poor. He said that so much had been written on the development of sanatoria and by those abler than himself that he thought it well only to touch briefly upon the subject. Dr. Boddington's attempt in 1840 was the first institution of the kind in this or any other country, and it was more than 19 years after that time that the Brehmer Sanatorium in Görbersdorf was opened and to Dr. Brehmer must be given the honour of being the first to systematise the so-called "open-air" treatment of consumption. Dr. Dettweiler, in 1874, followed with the Falkenstein sanatorium. In 1888 the celebrated Nordrach Colony was opened under Dr. Walther. Now there were sanatoria in nearly every part of Germany, both for patients able to pay as well as for the poor. The recent development of the sanatoria in Germany was partly due to the action of the insurance companies who found it economical to erect these institutions for the treatment of the consumptives. In this country they had many recently built sanatoria for paying patients, but as regards the poor they were certainly far behind the Germans and the Americans. The French, too, had several institutions building, or complete, for their poor, and the Sanatorium d'Agincourt, built by l'Assistance Publique, with 50 beds, was opened last year. It was stated at the Berlin Congress on Tuberculosis in 1899 that phthisis had increased in every European country except Great Britain during the last 40 years, and that in Great Britain the mortality from this disease had declined by 50 per cent. within that time. Notwithstanding that decrease, it was stated by Dr James Alexander Lindsay, in his address on the "Problem of the Consumptive Poor" at the opening of the session of the Ulster Medical Society in 1897, that there were in these islands 200,000 persons suffering from phthisis who might seek hospital relief, and there was only one bed for every 200 phthisical patients who might be expected to demand and require hospital relief, and in order to prove that he had not exaggerated he quoted from Sir Hermann Weber, that "well-arranged special hospitals for the treatment of consumption have accommodation only for one sufferer in a thousand." Dr. Walters, in his "Sanatoria for Consumptives," estimated the total number of beds for poor consumptives in hospitals and homes at 1270, which would be one bed to 1590 people, if they accepted the figures given by Dr. Lindsay, but they knew that their hospitals admitted other diseases than phthisis to their wards, which fact much reduced the available accommodation for the consumptive poor. When they looked for the special sanatoria to which to send their poor sufferers they found how few they were and how difficult it was to get admission for a patient to them. If there were an adequate number of sanatoria the special hospitals would be much relieved, their position would become readjusted, and they might become more in the nature of clearing houses, the patients being sent either to the wards for observation and treatment or direct to the country sanatoria. An exception must be made in the case of the North London Hospital for Consumption, Mount Vernon, Hampstead. They hoped the poor-law guardians of Metropolitan unions would carry out their intentions of erecting suitable sanatoria where such patients under their charge who were at all likely to benefit from the open-air treatment, might be sent, whilst separate wards in the infirmaries might be maintained where in the less hopeful or the hopeless cases the patients might be kept apart from the other inmates. This had been done in several urban Poor-law districts. The National Association for the Prevention of Consumption and Other Forms of Tuberculosis, to which the whole nation should be most grateful, had awakened the public of this country and it was fervently to be prayed that this International Congress, which they had so wisely convened, might be the means of provoking further public efforts to eradicate the scourge of phthisis, which they had now been taught was not one of an hereditary nature to which they must calmly submit, but one that might be tackled and subdued. Lieutenant-Colonel Montefiore endeavoured to point out in his paper that the "colony" system was the wisest upon which to establish sanatoria for the poorer sufferers, and he mentioned what had been done to give the poor the benefit of the open-air treatment by the London hospitals for consumption and by private philanthropic endeavours. He also showed some of the difficulties which beset the charitable worker in assisting the phthisical poor under the new condition.

Dr. BONNET-LÉON (Paris) explained the function of the anti-tuberculous dispensaries in France which as far as possible gratuitously provided to the poor—(1) education for the prevention of tuberculosis; (2) medical advice in as early a stage as possible; and (3) necessary assistance, especially in the proper providing of food. The results of these were highly satisfactory.

The Rôle of the Consumption Hospital in the Prevention and Treatment of Consumption.

Dr. J. EDWARD SQUIRE, physician to the North London Hospital for Consumption, communicated a paper upon this subject in which he said that for the cure of tuberculosis of the lungs hospitals for consumption were useful in proportion as admission was not restricted to the early cases. The hospital, to be complete, should provide for all stages of the disease—for those persons who with medical assistance could continue at work and also for those who were past work and past cure. To fulfil these requirements the hospital should have several departments: 1. Dispensaries or out-patient departments situated in the more crowded districts where tuberculosis was prevalent. The prophylactic rôle of this department in teaching patients how to prevent infection was as valuable to the community as the treatment was to the individual patient. 2. In-patient departments in some healthy situations removed from, but within easy access of, the poorer districts from which cases would be derived. Here amelioration rather than cure was the main aim, but the temporary isolation and the education of the patient in preventive requirements were valuable in prophylaxis. 3 Sanatoria in the country to which curable cases could be drafted for more prolonged stay than could be permitted in the hospital itself. The education in practical hygiene which patients received during residence in the sanatorium had far-reaching influence in prevention. 4. Homes for advanced consumptives which were practically isolation hospitals for the most dangerous class of cases who from poverty would otherwise be living under conditions in which the risk of infection would be greatest or who would be admitted into general hospital wards or poor-law infirmaries to the danger of other patients.

Dr. CALMETTE (Paris) communicated a paper upon Urban Dispensaries for the Prevention of Tuberculosis among the Working Classes, and was followed by Dr. L. PETIT (Paris) who described the Sanatorium of Mont des Oiseaux. Dr. SIEGMUND MORITZ (Manchester) detailed the [illegible] Treatment at the [illegible] Diseases of the [illegible] F.R.I.B.A., who laid down the main lines on which a sanatorium should be constructed with regard to site, elevation, and sewage disposal, and described the buildings at Harlaching (Munich), Falkenstein, Rupertshain, the Nurnberg Heilstätte (Engelthal), the Volksheilstätte Krailing (Planegg), Nordrach, Crookesbury Ridges, and Pine Wood. He also gave a description of the new sanatorium which is about to be erected at Frimley from his designs in connexion with the Brompton Consumption Hospital.

SECTION II.

MEDICAL, INCLUDING CLIMATOLOGY AND SANATORIA.

THURSDAY, JULY 25TH.

Sanatoria for Consumption.

The work of the section was punctually resumed by the delivery of an opening address by Professor CLIFFORD ALLBUTT (Cambridge) on the subject of Sanatoria for Consumption. The speaker began by pointing out that though the modern open-air treatment of phthisis might, perhaps, be successfully accomplished at home the method needed the supervision of a medical man with practical experience of the treatment as carried out in sanatoria. The effect of cold air was to increase the appetite and it did away with the necessity for forced feeding. The valuable scientific work carried out at sanatoria should be systematically calculated and utilised. The degrees of cure were three—arrest, obsolescence, and *restitutio ad integrum.* Obsolescence required two winters and one summer and was out of the question for the poor. To secure what might be called an "economic cure" six months would be necessary in the majority of cases. The dulness and emptiness of the lives of patients at sanatoria should be remedied by tranquil occupations and suitable forms of amusement. Professor Allbutt put the following questions to the meetings: Can mixed infections be inferred from fever curves? Is it possible to distinguish between economic cure and complete cure? How long is a febrile patient to be kept in bed in the reasonable hope of recovery? What can be based upon physical signs alone in regard to prognosis? Is multiple tuberculosis a condition too far gone for treatment in a public sanatorium? Of what use, if any, is massage or hydrotherapeutics? Are pulmonary gymnastics of use, if so, when and how?

Dr. J. KINGSTON FOWLER (London) said that the treatment of the tuberculous patient could not be carried on at home. Further researches on metabolism were requisite to enable them to say definitely what should be done in feeding patients. Early treatment was advisable and this was shown from the large proportion of post-mortem examinations disclosing tuberculosis arrested in the early stages and the small proportion found where a cure had taken place in the advanced stages of the disease.

Dr. R W. PHILIP (Edinburgh) pointed out that the temperature of the ward was best kept not too high. As a matter of fact patients did better in the winter than in the summer. The study of the temperature and pulse should guide the amount of exercise. Patients, if possible, should be treated in their native air.

Professor SCHRÖTTER (Vienna) explained that in Austria before sending patients away they were kept under observation at a central sanatorium and then their ultimate destination was decided upon.

Dr. DVORAK (Prague) urged that tuberculous patients should be relegated to isolated pavilions.

Dr. JANE WALKER (London) insisted that the mental con[illegible] be considered as well as their [illegible] patients could be employed in [illegible]stitution.

Professor JANEWAY (New York) said that it should be the duty of the State to prevent infection from tuberculous patients sent into the country. More exactness in the diagnosis of the early signs and symptoms of phthisis was required from the medical man.

Sir HERMANN WEBER (London) advocated a system of [illegible] sanatoria and discussed the subject of gout being a [illegible] disease.

[illegible] read a paper entitled a [illegible] for Children especially for [illegible] of Scrofulous Complaints. In former times, he pointed out, the so-called scrofulous diseases were much discussed by the medical profession and the public, but now comparatively little attention was paid to them, while the more fatal pulmonary tuberculosis commanded general attention. Yet there was good reason why scrofulous affections should in an equal measure engage their sympathy and attention, firstly, because they were likewise of tuberculous nature and intimately allied to other forms of tuberculosis, and often led to pulmonary or to acute meningeal tuberculosis; and, secondly, because they caused infinite suffering and misery to the patient and often death or invalidism or a crippled state for life By treating scrofulous affections they therefore not only endeavoured to cure the existing diseases but also to prevent pulmonary tuberculosis The principal means of cure were life in the open air, good food, hydrotherapeutic measures, active or passive exercise, and surgical treatment. These measures could not be carried out at the homes of the children of the poor, and frequently even not at the hospitals of large towns; but in the pure air of the seaside (and also of inland places, especially at high elevations) the treatment, if commenced early, almost always resulted in complete cure. Those who were rich could make the most necessary arrangements in private houses or establishments, but the children of the poor had no chance excepting in sanatoria, and for the majority of them sanatoria at the seaside were preferable to those inland, on account of the more vivifying effect of the sea air, which underwent constant changes by the regular local currents of air and by the stronger general winds, and on account of the facility of bathing in the open sea or in tepid sea-water. The poor children who were most benefited and who specially required the sanatorium treatment were those recovering from acute fever, those affected with deficient nutrition, anæmia, rachitis, scrofulous and tuberculous swelling of the lymphatic glands, a scrofulous inflammation of the skin or joints, including hip-joint disease and Pott's disease, and sufferers from adenoid affections of the throat and nose. For the treatment of the majority of these cases it was not sufficient to use any ordinary house—a properly arranged sanatorium was required. The number of children who required sanatorium treatment at the sea-side was very large, and the number of beds available for them in England was very small. There were perhaps 300 beds in the sea-side sanatoria of England, while 5000 would certainly not be too many. Every hospital for sick children ought to have a sea-side branch. It was almost incredible that there should be this strange defect in the hospital accommodation of England, especially when they reflected that the whole of the United Kingdom had such splendid sea-coasts and when they further considered that England was the first country to awaken to the great importance of this matter by establishing, on the suggestion of Dr. Lettsom and Dr. Latham, the General Sea-bathing Infirmary at Margate in 1791. The crying need for help and the possibility of affording this help must be unknown to the philanthropists of this country. If they were aware of the great sufferings which the poor children affected with Pott's disease of the spine, with hip-joint disease, with caries of bones, or with tuberculous inflammation of joints underwent in their wretched homes and how large a proportion of them became consumptive later or cripples for life, or died after protracted misery, and if they knew at the same time that the majority of them could be cured entirely and that many of the others could be restored to such a condition that they could earn their bread and could enjoy life, provided that they were sent early enough to sea-side sanatoria, many philanthropic persons would surely assist in supplying means to found numerous such establishments.

Dr. KNOPF (New York) recommended that patients should not be sent to sanatoria too far away from home because homesickness was a factor in delaying recovery.

Dr. W. V. SNOW (Bournemouth) advocated the treatment of tuberculous patients in sanatoria before any attempt was made at home treatment because of the advantage of learning discipline and proper management.

Dr. ROSENTHAL (Copenhagen) suggested that country hospitals should be utilised for the open-air treatment while sanatoria were being erected.

Dr. BURTON-FANNING (Norwich) discussed the value of rest for tuberculous patients; this with good nursing and attention to diet resulted in 92 per cent. of the cases in an institution which he was interested in gaining weight. One of the most unfavourable signs was frequency of pulse without fever.

Dr. WOLLF BECHER (Berlin) said that in Berlin there was provided for the poor a day sanatorium in the woods outside the town.

Mr. C. BRAINE-HARTNELL discussed the importance of noting the temperature after exercise and how long it remained high, stating that it should fall within 30 minutes. The rectal temperature was very useful as it showed variations which might otherwise be overlooked.

Dr. A. R. PARSONS (Dublin) put forward his views in regard to the possible inutility of the sanatorium treatment for the very poor. The value of the treatment depended to a certain extent upon the amount of time given to it.

Sir R. DOUGLAS POWELL, in the absence of Professor Clifford Allbutt, closed the discussion and commented on the necessity of recognising the fact that tuberculous patients required something in which they could take a little human interest.

FRIDAY, JULY 26TH.

There was no discussion in this section on Friday, but several papers of interest were read, of which we give *résumés*.

Dr. E. SYMES THOMPSON, consulting physician to the Hospital for Consumption, Brompton, read a paper with the following title:—

The Open-air Treatment in Institutions and in Nursing Homes.

He pointed out the difficulty, often insurmountable, of carrying out the "open-air treatment" in the houses of the patients, giving reasons for this want of success. He showed that balconies and "shelters" were superior to rooms even when the windows were reversed. He gave suggestions and details of treatment as regulated (1) by temperature charts by which the rectal and mouth temperatures were compared, because the mouth temperature was not an adequate guide for treatment; (2) by watchful consideration of respiratory movements; and (3) by discriminating attention to the digestive system. Whilst affection of the larynx was a late manifestation of tuberculous disease, pharyngeal affection was an early, often the earliest, symptom. Indeed, in very many cases the tubercle thus gained access to the system, and it was in cases of tuberculous pharyngitis prior to the development of lung affection that careful local and constitutional treatment in a nursing home often proved of the greatest prophylactic value. Whilst foreign health resorts retained their value in many cases English resorts for open-air treatment, and especially those at the sea-side, were, he considered, of equal value in some, and of greater value in other, conditions. The paper concluded with a condensed record of a series of 16 cases, from which the deduction was reached that in rapid cases (galloping consumption) nursing home treatment was the best. In many slight cases the evil was arrested in such homes more successfully than in other ways, and in advanced cases of long standing lasting benefit was often thus recorded.

Dr. W. EWART, senior physician to St. George's Hospital and to the Belgrave Hospital for Children, read a paper entitled—

Time-saving Methods of Treatment, with a Preliminary Note on the "Silver Treatment" of Phthisis by Intravenous Injections of Protargol.

A strong plea, he said, should be entered in the interest of the rate-paying public as well as of the patients for an adequate inquiry into the comparative capabilities of the various "cures" now available. Early and mild cases in strong subjects were practically self-curable with an open-air life; but with the large group of pyrexial, sub-pyrexial, or more or less chronic phthisis the open-air treatment, at any rate in this country, and also the climatic treatment, it would seem from Alpine experience, were not the shortest ways to a cure. A good deal of catarrh was remediable by what may be termed the hospital treatment, or "thorough" treatment, the object of which was to rid the case as soon as possible of its dangerous complications—bronchitis, catarrh, caseation, and suppuration—whilst utilising the period of unavoidable confinement in bed, in the ward, or in an even temperature for the application of every therapeutical influence which in the individual case might be profitably resorted to. This idea had been recently carried out with an encouraging degree of success in a limited number of cases. The favourable results obtained had demonstrated to his satisfaction the advantage of not sending the patients to the open air prematurely, but only in a convalescent state. He was not acquainted with the latest development of Dr. R. Maguire's formaldehyde injection treatment, but some of the results obtained with the original method were very favourable, although neither by this nor by any other method had a permanent clearance of the bacilli from the tissues been obtained. He was led to substitute protargol for formaldehyde by the conspicuous success of the administration of nitrate of silver in pneumonia (Caccianiga) and of its subcutaneous injection in phthisis (Mays). Pending the discovery of some better remedy he had provisionally adhered to it in preference to formaldehyde because of its more decided, of its more rapid, and of its more lasting action. The clinical effects resembled those obtained by Dr. Maguire with formaldehyde—viz., a remarkable subjective feeling of improvement coinciding with manifest improvement in aspect and in strength, a rapid diminution in the cough and in the expectoration, and a more or less rapid change from the dense sputum of phthisis to simple catarrhal sputum and ultimately to hyaline mucus The *ultimate effect was to lower the temperature*, but meanwhile the level might be disturbed by elevations incidental to the treatment More often than not the injection was followed after one hour by a chilliness or even a rigor and a sharp rise lasting about half an hour After this had passed off the patient felt and continued to feel remarkably well; no untoward symptoms of any kind had followed the injections A short attack of nephritis occurred in one patient, but this seemed to have been occasioned by a chill Pre-existing albuminuria of long standing was much reduced in one of his cases, in another the first injection succeeded in stopping a rebellious hæmoptysis The injection consisted of 40 cubic centimetres of saline solution containing from one and a half to two and a half grains of protargol, and this was preceded and followed by an injection (through the same needle) of a few cubic centimetres of pure saline solution to obviate leakage of irritating fluid into the tissues, from 12 to 15 injections generally sufficed. It was best to administer them at intervals of one day, but in some cases they had been given daily The protargol injection method had yielded by itself satisfactory results, but it did not claim to be more than the first and most important instalment in an extensive system of active treatment His present practice was to combine with it as soon as the case had lost all acuteness, general massage, gentle exercise, and particularly respiratory exercise for the expansion of the lung, strong diet and nutrient adjuncts, local and general treatment of the skin, and suitable internal remedies, among which he had obtained specially good results from ichthyol, originally recommended by Wertheimer This combined treatment had enabled some patients with originally unfavourable prognosis to become, after a very few weeks' stay in the hospital, quite suitable for the open air treatment, and to return, after a short period in the country, greatly improved and with a promising forecast of ultimate recovery

Dr A. BÉCLÈRE (Paris) read a paper on

The Technique of the Application of the Roentgen Rays in the Diagnosis of Tuberculosis

The subject under examination should recline on his back or be seated on an elevated chair, the height of which could be regulated like a music stool, and having the shape of a bicycle saddle, so as to permit of almost complete extension of the thighs over the pelvis The observer, to be in possession of a high degree of sensibility to the light, should stay some minutes in the dark before commencing radioscopic examination Precise measurements had taught him that after staying for ten minutes in darkness the sensibility of the retina to the light of the fluorescent screen became from 50 to 100 times greater than it was before, it became about 200 times greater after 20 minutes' darkness, and when this time was passed it increased still more. It was desirable that the generator of electricity for supplying the Crookes's tube should have a certain power, but it was not necessary that this power should be very great He used a small Wimshurst's static machine with four plates The machine could be put in motion by the hand, with a crank, and being not too large it was very easily transportable, it was good enough to furnish to an eye, sufficiently prepared by darkness, an excellent representation of the thoracic organs on the fluorescent screen. On the other hand, it was indispensable that the power of penetration of the Roentgen rays, varying as it did with the electrical resistance of the Crookes's tube, should, all things being equal, be exactly adapted to the luminous sensibility of the observer In the course of prolonged radioscopic examination the electrical resistance of the tube should diminish in proportion as the luminous sensibility became greater Measured by the duration of the equivalent spark by means of the *spentermètre* (the small instrument he had had constructed for this purpose), it would diminish from about nine centimetres to three centimetres or less For this reason the tubes furnished with a vacuum regulator were preferable to others, for in these a person could vary at will, according to the degree of vacuum the electric resistance and consequently the penetrating power of the rays. It was equally indispensable that the tube should be easily moved and capable of being placed over any part of the thorax which the observer wished This condition was fulfilled by the frame for carrying the tube which he had had constructed for the purpose But it was necessary, above all, to be able to restrict at will the divergent bundle of Roentgen rays which traversed the thorax so as to confine the surface illuminated by the screen, by this means were increased considerably the sharpness of outline and the definition of details in the radioscopic image of the region which the observer particularly wished to examine To this end he had had constructed a disc of lead with a variable aperture, which was a simplification of the iris-diaphragm of microscopes This diaphragm, close in front of the Crookes's tube and moveable with it, was completed by a small instrument—the incidence indicator—which showed at each instant in the course of radiographic examination, what was the position of the tube and the attitude of the patient and the point of the screen on which the rays impinged at right angles; it was in the immediate neighbourhood of this point, called the *point of normal incidence*, that the radiographic image approached most closely in form and dimensions those of the corresponding organ Thus in the radioscopic examination of a patient attacked by, or suspected of, tuberculosis they commenced by taking a general view of the thoracic organ, by enlarging to the maximum the opening in the diaphragm, then they pulled out the tube in such a way that the normal ray of incidence traversed the apex of the chest, then they narrowed the opening in the diaphragm until no more could be seen on the screen than the supra clavicular regions of the two lungs Lastly, he varied the electric resistance of the tube, and consequently the penetrating power of the rays, so as to obtai[illegible] the clear and obscur [illegible] were the conditions [illegible] the diagnosis of incipient pulmonary tuberculosis more exact and more certain.

Dr BONNET LÉON (Paris) read a paper on

The Use of Roentgen Rays for Diagnostic Purposes in Pulmonary Tuberculosis,

in which he presented the results of more than 600 personal observations Most of these cases were examined from 1897 up to the present time and had been as a preliminary submitted to the auscultation of various of his colleagues. By the use of the fluorescent screen alone the diagnoses were confirmed in 98 cases out of 100 and very frequently even at *the very outset of the disease*. He recommended the method when a large number of patients were to be examined at a time in noisy places and described a new process by which, he said, an easy and almost general diagnosis could be made in the pre tuberculous period when neither screen examination radiography, auscultation, nor the microscope revealed the least opacity, the smallest modification of the vesicular murmur, or the bacillus He laid stress on the diagnostic importance of anomalies in the synchronism and amplitude of movement of the two halves of the diaphragm in their rise and fall, and concluded by expressing an opinion that a radioscopic examination should be made of all patients predisposed to tuberculosis by heredity, alcoholism, contagion, or surroundings From a therapeutic point of view he would prescribe the methodical exercise of the diaphragm and the muscles of inspiration by respiratory gymnastics in accordance with the results of the radioscopic examination.

Dr ESPINA Y CAPO (Madrid), Professor in the Provincial Hospital of Madrid and Inspector of Public Health read a paper on the same subject in which he said that radioscopy as a means of diagnosis in tuberculosis constituted one of the means of which the greatest hopes had been formed. In the Congress held in Paris they could not speak so affirmatively as they could now because they were not then in possession of positive instances which would leave no room for doubt Radioscopy, in the case of tuberculosis, served as a potent means of settling the topography of the lesions Also by radioscopy the movements of the diaphragm, both in inspiration and expiration, could be appreciated. These movements under normal conditions were not so rhythmical and symmetrical on both sides in tuberculosis In tuberculosis the diaphragm did not rise to the same height on the sick as on the healthy side, and when the two lungs were affected the ascension was shorter on the worse side Dr Espina y Capo concluded by pointing out the different uses to be made of radioscopy and radiography and explaining the technique that he preferred.

Dr ALLEN T HAIGHT (Chicago) made a communication upon

Tuberculosis of the Eye,

in which he pointed out that the history of tuberculosis in the various parts of the eye was very interesting Ocular disease he considered to be often the earliest manifestation of tuberculous affection, and in support of this view he quoted numerous authorities and conclusions, with many tabulated and published cases. He concluded that in some cases early enucleation of the affected organ would save many lives.

Dr. **ALBERT JOSIAS**, physician to the Hôpital Bretonneau at Paris, and Dr. **JEAN CH. ROUX**, ex-intern of the Hospitals of Paris, communicated a paper on

The Treatment of Pulmonary Tuberculosis in Children by Raw Meat and Muscle Serum, according to the Method of M. Ch. Richet and M. Héricourt.

They had carried out the treatment by raw meat and muscle serum, as described by M Richet and M. Héricourt, in a series of tuberculous children. Each of the patients received daily the expressed juice of 500 grammes of raw meat; cooked meat was banished from their diet and an equal quantity of raw meat was substituted. Treatment was strictly maintained for months, and in some cases for nearly a year. Sixteen cases of pulmonary tuberculosis were investigated in this way, but of this number four had been left out of account, as they had only been under treatment for a few weeks. The course of the remaining 12 had been followed with great care, observations being made almost daily, and the results were very accordant. In only one case was the patient in the first stage of the disease (consolidation of the apex with some crepitation, but no breaking down). This patient was at present cured, her weight had risen by 10 kilogrammes; in seven months she increased from 29 to 34 kilogrammes. Four patients were in the second stage of pulmonary tuberculosis (more or less extensive infiltration, with softening, but no cavities). Two of these could be considered as cured after four months of treatment. In these patients all the signs showing a tuberculosis in process of evolution had disappeared. The condition of one was stationary from the point of view of pulmonary lesions; another patient improved, but left too soon. Seven patients were in the third stage of pulmonary tuberculosis (infiltration with softening and cavities). The general condition of six of these was bad, and they were near the terminating period of the disease In spite of treatment they grew worse, and death supervened in a period of time varying from one to three months after the inception of alimentation by raw meat. One little girl only, in spite of advanced lesions and a cavity in the left lung, maintained a good general condition. After 10 months of uninterrupted treatment she was evidently on the way to improvement. Their conclusions could but confirm what they had said in a preceding paper. So long as they had to deal with a purely tuberculous lesion the patient markedly improved under the treatment; auscultation revealed an arrest of the tuberculous process, and the patient recovered. While saying, however, that the cure could become permanent, it must be remembered that the future of the patients was the sole criterion of their complete recovery. But when the tuberculous lesion was invaded by microbes which grew in the softening lungs and in the cavities, when the organism was radically affected by toxins circulating in the blood, treatment such as they had carried out had no longer any therapeutic effect in the large majority of cases.

Dr. **R. MAGUIRE** (London) then read a paper upon

The Inhalation of Formic Aldehyde in the Open-air Treatment of Pulmonary Tuberculosis.

A great amount of experimental work, he said, had been carried on on the continent, in America, and in England, which went to prove that formic aldehyde was a powerful antiseptic and germicide, its bacterial action being equal to, if not greater than, that of bichloride of mercury. It was, he thought, rapidly superseding the older antiseptics, such as carbolic acid, perchloride of mercury, and others. Its advantages were: (1) it was non-poisonous and non-corrosive; (2) it could be used in the form of vapour, which, being of low specific gravity, was diffusible and mixed well with the air; (3) it had no action on clothes, textile fabrics, leather goods, and general household articles, or on metals, except iron and steel; and (4) it was easy and clean in its application, could be used as a general antiseptic and deodorant, and in the disinfection of rooms. About two years ago in the course of some experiments the author made the following observations. 1. Linen strips dipped in broth cultures of staphylococcus pyogenes aureus and exposed in a sealed room with a capacity of 2000 cubic feet to the vapour generated from 20 paraform tablets showed no growth after six hours. 2. From ½ to 1 per cent. formalin solution killed a pure culture of staphylococcus pyogenes aureus, bacillus anthracis, bacterium coli commune, and bacillus typhosus within from 30 minutes to an hour. And ever since he had found formaldehyde to be most efficient and reliable in the disinfection of rooms in the sanatorium with which he was connected. He began treating his patients, he said, with the drug in 1899, and had published the results of seven cases of which three were cured, two were benefited, while in two others the results were not conclusive. He now wished to record the results of 15 cases. Of these 15 patients five (all men) were completely cured. No physical signs or bacilli were found when they left. They had ever since continued to be in good health. Seven (six men and one woman) were almost cured—i.e., a few dry crepitations and a few bacilli remained when they left, but they had been in good health and had followed their different avocations. One (a woman) was slightly benefited. In the rest it had very little effect. Of the five who were completely restored to health three had affection of one lung, one had a large cavity in the left apex, and the other had marked signs of breaking down of both lungs. Of the seven who were nearly cured two had cavities of one lung and consolidation of the other, one had empyema complicating pulmonary tuberculosis, and the rest had more or less extensive affection of both lungs. After describing the technique employed Dr. Maguire concluded as follows:—1. The results of the treatment to his mind had been very satisfactory, and he would strongly urge that the drug should be given a fair trial in every sanatorium where the open-air treatment was carried out. 2. It should be systematically and persistently used and someone enthusiastic in the treatment should take charge of the apparatus—for the apparatus required to be kept clean and the lamp, &c., needed careful supervision every day; any neglect would bring about indifferent vaporisation and the results would be more or less a failure. 3. Though formaldehyde was non-poisonous it hastened coagulation of blood. Hence the injection of formalin directly into the veins and tissues of the body complicated the process of treatment and added a certain amount of risk. Besides, it was not necessary as the efficacy of the drug could be equally obtained by simpler methods of some form of inhalation already discussed in the paper.

Papers were also read by Dr. **CERVELLO** (Palermo), on the Value of Igazol, a preparation containing Formaldehyde; by Dr. **CHOWRY MUTHU** (London), on the Therapeutics of Formaldehyde; by Dr. **HUGH WALSHAM** (London), on the Use of the Roentgen Rays in the Diagnosis of Tuberculosis; and by Dr. **STCLAIR THOMSON** (London), on the Treatment of Tuberculous Laryngitis.

The closing incident in the last session of this section arose from the sad loss lately suffered by the President, Sir Richard Douglas Powell. After Dr. **THEODORE WILLIAMS** had made a sympathetic reference to the calamity that had befallen their President, Sir **J. W. MOORE** (Dublin) proposed and Dr. **DENISON** (Colorado) seconded the following motion which was unanimously adopted:—

> That Section II. desires to express its high and grateful appreciation of the able, dignified, and courteous manner in which Sir Richard Douglas Powell has discharged his presidential duties under most trying and regrettable circumstances; and the Section would convey to Sir Richard and Lady Douglas Powell an expression of its deep sympathy with them on the occasion of the death of their soldierly and heroic son in the South African campaign.

SECTION III.

PATHOLOGY, INCLUDING BACTERIOLOGY.

THURSDAY, JULY 25TH.

This section resumed work under the chairmanship of Professor **G. SIMS WOODHEAD**.

Professor **C. BENDA** (Berlin) opened a discussion on

The Varieties of Tuberculosis.

These, he said, depended first upon the character of the organism and secondly on the mode of dissemination. Tuberculous periangeitis began outside contiguous vessels. Endangeitis was from within and spread longitudinally. The fresh tubercles arising in the course of the chronic disease were from chance tubercle bacilli carried by the blood.

Professor **D. HAMILTON** (Aberdeen) said that it had to be decided whether the mucous membrane of the stomach was able to absorb the bacilli and to pass them on to the glands without itself becoming tuberculous.

Dr. **HABERSHON** (London) said that two of the chief paths of entrance were the tonsils and the lower part of the small intestines. Differences in appearance of the tuberculous lesions were from a difference in virulence of the bacilli.

Professor **OSLER** (Baltimore) felt certain that the frequency of tuberculous pericarditis was directly in proportion to the care with which it was sought.

Sir **CHRISTOPHER NIXON** (Dublin) thought that the virulence of the bacilli caused the different pathological conditions known as tuberculosis. Occasionally tuberculosis arose in man from cattle

Professor **ADAMI** (Montreal) thought that there was a constant physiological passage of bacteria through the tonsil and intestine. This explained how tubercle bacilli could be absorbed.

Professor **MUIR** (Glasgow) said that pulmonary lesions did not necessarily indicate that the disease was produced by inhalation, nor did the absence of lesions in the intestinal mucous membrane prove that infection had not occurred by that mode of entry.

Professor **HEYMANS** (Ghent) gave his experiences upon the diazo reaction in cases of tuberculosis in animals which were not altogether satisfactory.

The Comparative Virulence of the Tubercle Bacillus from Human and Bovine Sources.

Dr. M. P. **RAVENEL** (Philadelphia) then read his communication based upon three years' experiments with bovine and human tubercle bacilli. The experiments were of a very exhaustive nature and carried out with extreme care and efficient control. His conclusions in view of the statement of Professor Koch are extremely important and are as follows. The bacilli from the two sources had in culture a fairly constant and persistent peculiarity so that they could be tentatively differentiated. The bovine bacillus was for all experimental animals with the exception of swine more virulent than was the human bacillus. It was a fair assumption from the evidence which he produced, and in the absence of any definite evidence to the contrary, that the bovine tubercle bacillus had a high degree of pathogenic power for man which was especially manifest in the early years of life. In justification of the last deduction he quoted five cases of tuberculosis in human subjects which were directly derived from bovine sources.

Professor **SIMS WOODHEAD** thought that as the time for terminating the meeting had come and as the communication of Dr. Ravenel was of such great importance he should defer the discussion on the paper until the following (Friday) morning.

FRIDAY, JULY 26TH.

The Temperature Required to Kill Tubercle Bacilli in Milk.

Professor **BANG** (Copenhagen) addressed the section on the subject of the temperature required to kill tubercle bacilli in milk. His view was that anything under 85° C. was not certain to destroy the bacilli though it might be possible He concluded his very remarkable communication by explaining how the froth on the milk was below the temperature of the milk itself and thus the chance of infection might still remain.

Professor **RUATA** (Italy) took up the point that tuberculosis was admittedly a chronic malady, and that being so he came to the conclusion from the fact of the great number of deaths recorded from tuberculous enteritis and meningitis before infants had reached the age of two months that therefore [illegible] being so common a cause in [illegible] to sterilise milk they must use a temperature of 90° C and this did not in any way interfere with the making of butter and cheese.

Professor S. **DELÉPINE** (Manchester) considered that the necessary temperature was near 100° C. By experimental inoculation it could be shown that lower temperatures only caused delay in the symptoms of tuberculosis becoming manifest.

Dr. **MARMOREK** (Paris) gave it as his opinion that tuberculous meningitis must be secondary to some preceding tuberculous lesion and discussed the comparative immunity of the dwellers among the Alps who used large quantities of milk, but that milk came from the purest sources.

Mr. H. A. **KINGWELL** (London) said that much American meat arrived in this country infected with tubercle and with cysticerci, but Dr. **RAVENEL** did not agree to his statement that it was not difficult to find cysticerci in pig's flesh.

A discussion on

Mixed Infection in Tuberculosis

was opened by Mr. A. G. R. **FOULERTON** (London), bacteriologist to the Middlesex Hospital, who pointed out that the influence exerted by secondary infections on the course of tuberculosis began to attract attention as soon as the identification of the specific parasite enabled the pathology to be studied. In chronic pulmonary tuberculosis and in chronic pulmonary phthisis there could be no question as to the cardinal part which the bacillus tuberculosis played as a primary or original factor, but its importance as an ultimate factor in the mortality was not by any means so well established. The terms "chronic pulmonary tuberculosis" and "chronic pulmonary phthisis" were used in clinical medicine as if they were synonymous, but pathologically the two conditions differed widely. In chronic pulmonary phthisis the action of the bacillus tuberculosis had added to it the more acute influence of pyogenic organisms, the potentiality of which for evil was incomparably greater. By uncomplicated chronic pulmonary tuberculosis Mr. Foulerton understood the condition in the lungs which was brought about, usually in adults, by the presence of the bacillus tuberculosis alone and in which a limited number of granulomata were present. In such cases physical signs were most frequently absent and the discovery of the infection by the finding of bacilli in the sputum was usually a matter of accident. This condition must, however, in reality be extremely common, and its frequency might be estimated from the number of instances in which the lesions of arrested tuberculous infection were found in the lungs of adults dying from other causes. With respect to the secondarily infecting bacteria of chronic pulmonary phthisis, practically all who had worked at the subject were agreed that various species of cocci were the predominating organisms, streptococcus pyogenes, staphylococcus pyogenes aureus, staphylococcus pyogenes albus, diplococcus pneumoniæ, and micrococcus tetragonus being found most frequently. The pathogenic action of the secondarily infecting bacteria consisted chiefly in local destruction of the tissues, the production of perinodular pneumonia, and the setting up of toxæmia. The treatment of secondary infections in pulmonary phthisis should be the chief object aimed at. Under the influence of rest, and in an atmosphere of pure air, such as might be found at moderate altitudes, the virulence of pyogenic bacteria became attenuated and tended to die out.

Professor **WILLIAM OPHÜLS**'s (San Francisco) paper on the same subject was then read to the meeting. He had succeeded in finding pure cultures of tubercle bacilli in seven out of 13 cases of large cavities. Tubercle bacilli alone could be found in 25 cases of tuberculous pneumonia. In 12 cases of recent mixed infection there were tubercle bacilli with pneumococci, streptococci, or staphylococci. There was a general infection in six cases of mixed infection, where the pyogenic cocci were held to have caused acute septicæmia, being the immediate cause.

Dr. W. **BULLOCH** (London) suggested a joint committee of research by clinicians, pathologists, and bacteriologists to investigate and to report.

Dr. F. F. **FRIEDMANN** (Berlin) gave details of some experiments proving that a fœtus could contract tuberculosis from the paternal side without the mother being affected.

Dr. **HUGH WALSHAM** (London) read a paper on

Excretion Tuberculosis of the Kidney.

Excretion tuberculosis of the kidney, he said, was defined as the occurrence of secondary tuberculous foci by a process of excretion through the glomeruli and the bacilli had become arrested at some point in the tube, most often in the medulla of the kidney. 13 cases of disseminated miliary tuberculosis had been examined in proof. All tubercles that had advanced to the stage of giant-cell formation had to be rejected. In the vicinity of the giant cell the action of the bacilli appeared weakest and the bacilli found in the neighbourhood of giant cells were usually few on account of the phagocytic action of the giant cell on the bacilli (Metchnikoff and Stschastny) The view that giant-cell formation in renal tuberculosis was derived from renal epithelium was untenable. Very little was said by the authors of text-books on pathology as to the exact position of the bacilli in miliary tuberculosis of the kidney. The only British pathologist who mentioned the position of the bacilli was Hamilton whose description was very accurate. Details were given of the microscopical examination of tuberculous kidneys by serial section in four cases. The bacilli which gave rise to the process were found in the urine tubes only, or in process of expulsion through the tubes. It seemed probable that other pathogenic bacilli and cocci were excreted by these organs. Horton-Smith had admitted the possibility of a typhoid bacillus finding its way through the kidney to multiply in the bladder. Plate 10 of his (Dr. Walsham's) series illustrated a case of septicæmia. Two of the urine tubes were seen to be stuffed with micrococci; the surrounding tissue was free from them, but was infiltrated with pus cells. The experimental production of renal tuberculosis was discussed, especially Borrel's and Wyssokowitsch's experiments. One of the speaker's own plates (Plate 11) seemed to show a glomerulus in process of excreting the bacilli. Tubercle bacilli arriving by the renal artery either became arrested in the capillaries of the glomeruli or in a small twig of the renal artery, and here in most cases tuberculous changes arose. A possible cause of the non-excretion of bacilli (evidence of excretion being found only in four out of 13 cases) was the hindrance caused by large caseous foci of tubercle. If, as frequently happened, large foci of tubercle were found enclosing apparently normal urinary tubes which contained no bacilli, notwithstanding the quantity in the neighbourhood, it might be assumed that the bacilli had been conveyed by the blood or lymph-vessels. If, on the other hand, tubercle bacilli were found in a urinary tubule with little surrounding caseation the conclusion was that the bacilli did not enter the tube from the surrounding tissue, but produced the tuberculous nodule while in process of excretion by the kidney. The following conditions had therefore been shown. 1. The presence of tubercle bacilli within the glomeruli of the kidney without any visible change in the vessels of the glomeruli in the surrounding tissue. 2. The presence of bacilli in the urine tubes. 3 The presence of tuberculous changes in the neighbourhood of the bacilli in the tubes (tubercles of excretion). 4 The presence of bacilli in the urine of a patient who died from acute miliary disseminated tuberculosis.

The subject of the Transmission of Tuberculosis by Sipping Wine from the Same Vessel at the Communion was mentioned by Mr. **HERBERT MORGAN** and the Danger of Infection from Railway Carriages was dealt with by Dr. **BROOK HUNT**.

SECTION IV.

VETERINARY (TUBERCULOSIS IN ANIMALS).

THURSDAY, JULY 25TH.

Tuberculosis and the Milk-supply.

The discussion on this subject was opened by Mr. **JAMES KING**, Chief Veterinary Inspector to the Corporation of the City of London, whose important paper will be found in THE LANCET of July 27th, p. 245.

Sir **GEORGE BROWN** spoke on the necessity of stimulating the authorities to further legislative action, but he did not know how to do it, and if anyone possessed the secret he would like to hear it. The majority of meat inspectors throughout the country had not even read the reports of the Royal Commission with its recommendations, and therefore could not be accused of wilfully neglecting them.

Mr. **BOWEN-JONES** put forward a few propositions which he believed would lead to practical legislation without any great disturbance of the existing law. In order to get that the views approved of must be endorsed and supported by all. No legislation would be founded on any controvertible fact. He thought it absolutely useless to think that tuberculosis could be scheduled under the Contagious Diseases Act. He then detailed his propositions dealing with the meat laws in England. All confiscation should be paid out of the Imperial purse. Preventive measures other than those contained in the propositions should be voluntary.

Mr. **HOPKINS** praised the manner in which meat inspection was carried on in London, and if it was carried on in the same way everywhere else there would be nothing to complain of. He also thought that compensation should follow confiscation, and this was a great principle which should be demanded in Parliament thoroughly and without any tinkering.

Dr. **JAMES CAMERON** (Leeds) said that tabes mesenterica was often produced in children from the drinking of tuberculous milk. He also advocated a more thorough disinfection of the byres and other surroundings in which the cows were placed, and concluded with a wish for more unanimity of inspection, referring to the utter incompetency of some of the present inspection. All inspectors should be up-to-date, *bonâ-fide* veterinary surgeons.

Mr. **HEADLEY** (Northumberland) thought that Professor Koch's announcement had put the clock back 20 years. The county which he represented was the county which suffered most from the ravages of tuberculosis. Northumberland was the biggest cattle producing county, but there was no *bonâ-fide* inspection of meat. He also referred to a local association which compensated the owner by giving him two-thirds of the price of the animal.

Mr. **MATTHEW BRECHIN** (Glasgow) said that the compensation just referred to could not possibly be adequate. It was as well to remember that Professor Koch might be right and the treatment of this subject should not be too drastic. It was a remarkable fact that Glasgow lost far more meat by condemnation than London did, totally out of proportion to the population. Every butcher should be allowed expert evidence before meat was condemned and no obstacles should be put in his way provided he was carrying on business in a perfectly honourable way.

Professor **RUARDI** (Italy) said that tuberculous meat must produce first intestinal tuberculosis and secondarily pulmonary tuberculosis. However, an extensive examination of statistics showed that intestinal tuberculosis came on at a time when meat was not eaten—i.e., in infancy. He supported his contentions by referring to English statistics for 1899. In adults tabes mesenterica was secondary to phthisis, and yet meat formed the chief food of the adult. There must be no scientific doubt on any question on which they asked Parliament to legislate. They must remember that in experimenting upon animals the results were not necessarily similar in man. In his opinion inoculation was not of the least importance.

Mr. **COOPER** (London) said that the population of London had taken every care to see that their inspectors were highly qualified men. In some detail he called attention to the present condition of the law regarding seizures whereby the butcher was practically without means of defending himself from those who probably knew nothing about the matter. He suggested that medical officers of health throughout the country should have a conference and should arrive at a common line of action with regard to the inspection of meat which should be enforced throughout the United Kingdom. At present the law acted very badly and there was a premium for concealment. He showed the folly of following the example of foreign countries, for large quantities of foreign meat exported from abroad were seized as unfit for human food. He also advocated a more natural open-air life for the cows and cattle as being conducive to the best health. In England they might be kept out much longer than they were. At any future conference he suggested that all parties should be properly represented which certainly had not been the case with the Royal Commission.

Mr. **PEARSON** (Sheffield) said that London was very well circumstanced as regards meat inspection. If the British agriculturist fed his animals he would be at the loss, nor could the butcher afford to buy a "dead" animal. It must be admitted that when the agriculturist interest of the country was good the general trade of the country also was good. He insisted on the necessity of inspection.

Mr. **WILLIAM FIELD**, M.P., from an exhaustive study of statistics found that tuberculosis as a human disease had decreased by 50 per cent., whereas the amount of meat during the same time that had been consumed by the population had been trebled and he could not see much communicability of tuberculosis through the agency of meat in the face of that fact. The qualifications of meat inspectors had been improved to certain extents since he had brought the notice of the country in Parliament to their total lack of qualification, but the British law on the subject was in a state of confusion at the present time. He regretted that there was no representative of the trade on the Royal Commission To get effective legislation public opinion must be educated and Parliament must be shown that behind them they had the weight of that public opinion. It would, to insure speedy legislation, be necessary that the cost involved should be as small as possible.

Mr. **L. F. COGAN** (Northampton) said that the law as regards seizure was just as necessary in the case of pigs, though those animals had not been mentioned. He insisted very strongly on the necessity of the support of the press throughout the country. The choice of action lay between two things: either compensation must be given for destruction of animals in the public interest or the farmer would have to guarantee that the animals were sound when they were sold.

Councillor ANDERSON, M.D., (Glasgow), said that the principle of compensation was a very serious one, and if once admitted in the meat trade it might be taken as a precedent and applied to a great many other things. Full compensation would have a tendency to create a new class of men who might take unfair advantage of it. In Glasgow they had instituted a meat inspection committee and had made full provision for the defence of the owner of the diseased meat. The public should be protected with as little injury as possible to the trade.

Professor OWEN WILLIAMS (Edinburgh) said that there was not sufficient uniformity of inspection. The veterinary profession was of the opinion that the inspectors should be appointed by Government and not by the municipal authorities. It should be possible for the inspectors to be changed from town to town to avoid local influence. All slaughter-houses should be public. Compensation should not be permanent but gradually diminished and then abolished and finally confiscation should be made punishable after a certain number of years.

The AGENT-GENERAL OF NEW ZEALAND said with regard to the open-air treatment of cattle that tuberculosis was a great pestilence in Queensland and New Zealand, where the herds were out of doors all the year round. In those countries closest Government inspection was required by its veterinary inspector and it was made law that every town of 2000 inhabitants should erect public abattoirs. After slaughtering the meat was subjected to Government inspection. They paid the farmers for the value of the beast if diseased and its flesh was reduced by a steaming process to manure and was not given to pigs, the hoofs and the hides became the property of the Government and were sold for what they would fetch. This arrangement resulted in the farmers inviting the inspection of their animals if they were suspicious.

Mr. W. HUNTING (London) said that the only way to protect the public against tuberculous meat was to make the meat regulations part of a more uniform scheme under the Board of Agriculture for the stamping out of the disease at its source. It was illogical for the butcher to receive full compensation, for if he did there would be no necessity for him to try to control the disease. He thought that Parliament could only be moved in the face of a general election.

FRIDAY, JULY 26TH.

The Legislative and other Measures to Combat Tuberculosis amongst Animals.

The discussion was opened by Professor DUNCAN MCEACHRAN reading a paper on this subject which will be found at p. 279 of our present issue.

Mr. WILLIAM DUTHIE (Collynie Tarves) said that there was nothing more important than the yearly cleansing and disinfection of the byres. A proper system of ventilation was not yet generally understood. He thought that Aberdeen did not allow the cattle sufficient open-air and out-of-door exercise, but better arrangements in this respect were now beginning to obtain. If a cow had udder disease no calf was allowed to suck that animal. He strongly objected to the plan of condemning a valuable carcass for some very small tuberculous lesion, for there was no danger from the meat of such a carcass. If a carcass was destroyed it should be because of general diffuse tuberculosis. The fact that Canada did not give compensation was no reason why the British Government should not give it on a reasonable system.

Professor NOCARD (Alfort) then read a paper on

Tuberculosis in Bovine Animals: its Dangers, its Progress, its Prophylaxis,

in which he came to the conclusion that tuberculosis was one of the diseases of cattle which caused most loss to agriculture in all countries; that everywhere the disease was on the increase, forming everywhere a menacing danger to public health as well as to public wealth; and that infection being the only formidable cause of the increase of tuberculosis there was need for the adoption of legal measures prescribing (1) the complete separation of unhealthy from healthy animals; (2) the slaughtering without delay of those sick animals which showed clinical signs of the disease, and especially of cows attacked with tuberculous mastitis; (3) the interdiction from selling tuberculous animals for a destination other than the slaughter-house; and (4) the pasteurisation of all the sub-products of butter and cheese manufactories. On the risks involved to man from tuberculous animals he came to the following conclusions as to the best means of guarding against them: 1. That the resemblance of tuberculosis in men and in mammals was no longer denied. Healthy cattle-sheds had been infected by lengthened occupation by consumptive cattlemen The converse was equally possible, at least theoretically. 2. That meat obtained from tuberculous animals was rarely dangerous, and when it was dangerous it was only slightly so. The established regulations for the inspection of tuberculous meat would be sufficient to prevent even the shadow of danger if such regulations were applied always and everywhere, but unfortunately this was not the case. 3. That the milk given by tuberculous cows was rarely dangerous, but when it was dangerous it was most often so in a very high degree; hence the necessity of submitting cow-houses to a periodical inspection when the milk yielded was destined for public consumption. Cows being really only dangerous when they had a tuberculous udder the inspector's attention should be drawn to the state of the udder. Any cow showing clinical signs causing suspicion of the existence of a tuberculous mastitis or of serious visceral tuberculosis ought to be isolated at once pending the making of a diagnosis, this being easily and rapidly done by the present process; the milk should be boiled before being sold or consumed even by the animals on the farm.

Professor THOMASSEN (Utrecht), who spoke in French, cited four cases in which he had inoculated animals with cultures of tubercle bacilli from man, and he ventured to differ somewhat from the statement which had been made by Professor Koch. He also gave a *résumé* of some proposed legislation which was to be carried out in Holland with reference to tuberculosis. Animals affected with tuberculosis were to be destroyed and "reacting animals" were to be segregated. The importation of affected animals was to be interdicted.

Colonel NUNN (London) referred to the universal acknowledgment that it was desirable to eradicate this disease, leaving the matter of communicability out of the question. To an ordinary person the legislation on the matter was misleading. There appeared to be ample Parliamentary powers and it was their duty to educate the people to the point of moving the executive power.

Professor W. A EDGAR (Dartford, U.S A.) said that some of the colonies were beyond us in attempting to suppress diseases of animals, although the veterinary profession in this country had long been advocating the enforcement of enactments against tuberculosis. The possibility of accurately diagnosing the disease by tuberculin had removed the great obstacle to the placing of tuberculosis under the Contagious Diseases (Animals) Act and the suppression of the disease. They must take legislative steps without any further delay. Restrictive measures must be universal and uniform and not left to the "may if they think fit" of local authorities To ensure promptness and to stimulate local interest in the suppression of the disease the powers they had should be administered by the local authorities He could not agree that it was harmless to allow the skin of a condemned animal to be sold, as it was then used for manure.

Professor DEWAR (Edinburgh) made some remarks in connexion with the suppression of tuberculosis apart from legislation. There was a very exaggerated idea of the expense incurred by any individual breeder who was likely on his own initiative to start to clear his herds of the disease. It was the most profitable thing that a breeder could attempt and he gave figures proving this. Very little faith was now put in the hereditary transmission of tuberculosis.

Mr. W. HUNTING (London) said that there was some but very little legislation against tuberculosis, confined entirely to the protection of man There was supposed to be some protective legislation against tuberculous milk and meat, but it was not properly carried into execution. Four-fifths of the inspection were done by men who knew nothing about it and the remaining fifth was done by those who knew too much If it was particularly dangerous to keep a cow with a diseased udder in the shed, was it not more so to leave a lot of "wasters" in the sheds who were emitting bacilli from both ends the whole of their lives? This required legislation just as much as udder disease. The greatest obstacle to legislation was the ignorance of the laity regarding the causation of the disease. At the present time the butcher and the cowkeeper had to pay or be fined for all the tuberculosis which was put into their hands by the breeder and feeder.

Mr. POTTER (Paisley) wanted to know, in view of the vastly different opinions held by authorities, what education they were going to give the people?

Mr. F. J. LLOYD (London) said that it was absolutely impossible to make cheese from sterilised milk, as had been implied by a previous speaker. With reference to Denmark and the system of pasteurisation the object was to obtain a butter which would be of better and uniform quality for the British market. Persons were always too ready on insufficient evidence to attribute tuberculosis to the milk-supply. but the sterilisation of milk was not only a safeguard against tuberculosis but also against scarlet fever and other infectious diseases, though this was not frequently mentioned. In large towns want of sanitation was a more potent factor in the causation than the quality of the milk. There would not be the present difficulty of teaching the farmers that it was their duty to rid the herds of the disease if the veterinary profession had been of one mind in the past.

Mr. J. S. LLOYD (Sheffield) referred to the difficulty of seeing that ventilation was properly carried out. Meat inspectors should have a thorough training in their duties and should not hold simultaneously such a post as the inspector of nuisances. He regretted that the Meat Traders' Federation had joined issue with the agriculturists in asking compensation for diseased udders, which, in his opinion, with certain restriction was not fair or necessary.

Dr. C. PORTER (Shrewsbury) then read a paper on

The Measures Necessary for Improving Cowsheds and Insuring the Health of Milch Cows.

He pointed out that general legislation was urgently necessary for the following purposes:—1. To empower urban and rural sanitary authorities to inspect, in regard to tuberculosis and any other disease, cows and cowsheds, wherever situated, from which milk was supplied to their districts. 2. To endow county councils with concurrent powers. 3. To amend and to extend the provisions of the Dairies, &c., Order of 1885 so as to make applicable to tuberculosis its regulations concerning the inspection of cattle; to prohibit the use of milk from tuberculous udders as food for animals unless first boiled; and to provide for a sufficiency of moving air at the heads of milch cows kept in cowsheds. 4. To empower the Board of Agriculture to provide free tuberculin for testing the stock of all assenting owners. 5. The application to the kingdom generally of powers on the lines of the tuberculosis clauses of various local Acts, with the further powers of prohibiting the removal of suspected animals and of applying the tuberculin test. 6. The compulsory slaughter of all reacting animals, as it was impossible, except by an almost impracticable system of espionage, to insure their isolation and the disuse of their milk. 7. The payment of full compensation when the slaughtered animal was found to be free from tuberculosis and of substantial partial compensation when the disease was localised, but only in such cases. 8. Penalising the fraudulent use of tuberculin for "fortifying" purposes. 9. Protecting from personal liability sanitary officers acting *bonâ fide*, as per section 265 of the Public Health Act, 1875 Dr. Porter also considered that there should be reference in the model regulations to some cubic space requirements for cowsheds in sparsely populated localities; that periodical veterinary inspection of milch cattle was required; and that information in regard to bovine tuberculosis, and especially in reference to the value of the tuberculin test and the importance of feeding calves on wholesome milk, should be disseminated amongst farmers and cow-keepers.

Sir GEORGE BROWN, in concluding the business of the section, expressed his great satisfaction at the very large and enthusiastic audience which the section had attracted. He hailed with delight the oft-repeated statement that the traders, meat salesmen, and the farmer were all convinced of the great importance of taking every possible precaution for the purpose of getting rid of the disease in the lower animals. He sympathised with the butchers in the injustice to which they had occasionally to submit in regard to the question of seizures. He had called the attention of the Royal Commission to the waste of good meat unnecessarily in this matter owing to seizure by untrained men.

Mr. B ST. JOHN ACKERS proposed a hearty vote of thanks to the chairman, which was seconded and carried unanimously.

THE PATHOLOGICAL MUSEUM.

The museum of the Congress had been arranged under the auspices of the Museum Committee to give as far as may be a complete ocular demonstration of the disease of tuberculosis. An elaborate catalogue was drawn up and edited by Dr. W. Jobson Horne, the honorary secretary to the committee. It is a well-printed volume of some 200 pages, illustrated with plates, plans, and diagrams. The frontispiece gives a plan of the museum, which was held in the small Queen's Hall. Around the hall were arranged the morbid anatomy exhibits, at the platform end was the microscopic collection, and on the floor of the hall were photographs and drawings, together with an exhibit of bacteriology and experimental tuberculosis. Charts and diagrams hung on the walls.

In the bacteriological section the most interesting exhibits were those of the various bacilli allied to, or simulating, the bacillus tuberculosis. Such was Dr. Moeller's exhibit of the timothy bacillus, the grass bacillus, the butter-and-milk bacillus, and the excrement bacillus. Dr. Lydia Rabinowitch showed a very complete collection of acid-fast bacilli simulating that of tubercle, and Mr. Harold Swithinbank showed a set illustrative of "the hitherto supposed different varieties of the tubercle bacillus, acid-fast bacilli, and organisms of pseudo-tuberculosis and pathogenic streptothrices at different stages of growth." As regards experimental tuberculosis the most striking in view of Professor Koch's speech were the series exhibited by him of preparations illustrating the effects of inoculating cattle with the bacilli of bovine and of human tuberculosis. They certainly show that cattle, including pigs, are resistant to human tuberculosis. On the other hand, there was a series of water-colour drawings illustrating the results of experiments by the late Dr. William Marcet, details of which may be found in his communication to the Royal Medical and Chirurgical Society on May 14th, 1867, in which reference is made to Dr. Villemain's discovery that tuberculosis can be inoculated from man to animals.

The exhibit of the morbid anatomy and pathology of tuberculosis was very complete. The specimens were naturally for the most part taken from British museums, but there was a set of preparations illustrating tubercle of the cardiac valves, of the blood-vessels, and of the thoracic duct exhibited by Professor C. Benda of Berlin. Dr. Haushalter and Dr. Spillmann of Nancy showed 50 photographs illustrative of infantile tuberculosis. Dr. Hugh Walsham and Dr. Ernest W. Martin both showed some excellent skiagrams of the thoracic cavity mainly dealing with tubercle, but in one or two instances with pneumothorax and other non-tuberculous morbid conditions.

The Royal Veterinary College of London and the Royal College of Surgeons of England exhibited preparations showing the effects of tuberculosis in animals, while Dr. George Newman exhibited 23 microscopic slides showing the comparative pathology of tuberculosis in the animal kingdom The organs producing the specimens came from the Royal Zoological Society.

The remainder of the exhibition was taken up with charts and diagrams, photographs showing the effects of the open-air treatment, and sanatorium fittings. Dr. T. Glover Lyon showed a working model of his ventilating apparatus, Messrs. Maw and Son and the Sentinel Company of Cambridge exhibited sterilisers for milk, while Messrs. R. A. Lister and Co. of Dursley showed their filtering and pasteurising plant. The architectural section, which had been collected and arranged by Mr. Thomas Cutler, F.R.I.B.A., included photographs, plans, and drawings of various sanatoria. Altogether the exhibition was very complete and we think that the Museum Committee may be congratulated on the fruit of their labours.

THE SOCIAL SIDE.

A reception of the members of the Congress was held by the Council of the Sanitary Institute in the Parkes Museum on July 25th. Over 300 members availed themselves of the opportunity of visiting the Museum of Hygiene, including many of the foreign delegates attending the Congress. The visitors were received by Sir Joseph Fayrer, Professor W. H. Corfield, Mr. A. Wynter Blyth (chairman of the council), Dr. H. R. Kenwood (chairman of the Museum Committee), and other members of the council, and full information was given on all points of interest by the secretary of the institute, Mr. E. White Wallis.

The Earl and Countess of Derby received the members of the Congress at an At Home held in the Victoria and Albert Museum, South Kensington, on the night of July 25th. The reception was numerously attended and was characterised by the presence of an unusually large number of the leading lights in the scientific world. The wonderful specimens of the various schools of art were naturally the subjects of much admiration and the enjoyment of the evening was greatly enhanced by an excellent programme of music played by the band of the Grenadier Guards In another part of the building Karl Kap's Viennese Band was stationed and it was not until a late hour that the guests departed

Sir J Whittaker Ellis and Lady Ellis gave a most enjoyable garden party and river picnic at Buccleuch House Richmond, on the afternoon of July 26th The weather was not ideal, but the members of the Congress were able to avail themselves of a commodious electric launch which conveyed parties of the visitors up and down the lovely reach of the river Thames at the foot of the classic Richmond Hill Lady Ellis had made every arrangement for the comfort of her guests in case of bad weather and the company fully appreciated the hospitality of their hosts

The Duke and Duchess of Northumberland, in response to an invitation issued by them to the members of the Congress, received a very large company of guests at their mansion at Syon generally known as Syon House, on the banks of the Thames near Isleworth, on July 27th The Duke and Duchess had made the most elaborate plans for the convenience of their many guests, carriages were waiting at the various railway stations in the vicinity to convey the visitors to Syon The Duchess received the members of the Congress at the entrance to the long library overlooking the park and river The great beauty and elegance of the apartments traversed did not fail to excite the admiration and praise of the foreign visitors In the grounds commodious tents amply provided accommodation for refreshments, and a military band station [illegible]
audience [illegible]
great pleasu[illegible]
the afternoo[illegible]
careful of the guests made a speedy departure for London and they were wise indeed in their generation, for just before 6 P.M the rain fell in torrents and necessarily occasioned some discomfort

The Dinner to the Foreign Delegates

Lord Derby presided over the banquet given at the Hotel Cecil London in honour of the foreign vice-presidents and foreign delegates and also of the delegates representing the Indian Empire and British colonies The dinner took place on July 26th and was attended by about 300 guests Among those present were Lord Lister, Lord Reay, the Lord Mayor of London Sir William Church (President of the Royal College of Physicians of London) Sir Christopher Nixon (President of the Royal College of Physicians of Ireland), Sir Henry Norbury (Director General of the Medical Department of the Royal Navy) Dr J Dunsmure (President of the Royal College of Surgeons of Edinburgh) Dr J Andrew (President of the Royal College of Physicians of Edinburgh), Dr J Finlayson (President of the Faculty of Physicians and Surgeons of Glasgow) and a very large number of the best known medical and scientific men in the kingdom

The Chairman proposed the toast of The King and acknowledged the great debt which the Congress owed to His Majesty for the interest he had displayed in the campaign against tuberculosis which was due to his initiative He claimed that the King had been foremost in that movement in this country

The Chairman in proposing the toast of "Our Foreign Guests" said The toast which I now propose is one to which I hope and am sure that all Englishmen will do the greatest honour When we drink to the health of "Our Foreign Guests and when we consider who these guests are, surely nothing more is required to stimulate your enthusiasm and for once to let people see that the Englishman is not so cold a person as he is supposed to be All those who have come, possibly at inconvenience and who have brought to this Congress the tribute of their knowledge the result of their experiments, the help which they can afford by suggestion and by example to the brethren of their profession to these indeed we worthily pay honour We are glad to think that this Congress is not that of one but of many countries, and that it is a great international movement in which all can join with freedom and at the same time with a sense of comradeship and of relative support which must help on the movement in which we are all engaged We recognise, as we are bound to do in common candour, that we were somewhat behind in the race at first, that we had to borrow many of our ideas from foreign countries, that we had to copy much which was done, and that we had to try to emulate those undertakings which had been successful elsewhere In sanatoria, in the arrangements of hospitals in the separation of patients, and in the separation of those who hardly come within the description of patients we have learnt as we hope, many lessons From this Congress we trust that the combination of talent which has been brought together, that the friction of the various wits and intellects which have been brought around our council board will produce that result to which we look forward and that the conference will not be barren but will leave behind it an abiding good When I look on the formidable list formidable in numbers only, of the gentlemen whom I shall have to call upon to reply for their respective countries I feel that I must not take up too much of your time This however you will allow me to say, that while we thank our foreign guests for having come to us we are not satisfied only with that, but we would ask them—and we say it from our hearts as well as from our lips—to remember the cordial invitation we extend to them to come again We are cold, perhaps as some say phlegmatic, our 'Good bye' conveys a wish only for the future happiness and welfare of the individual to whom we say it, and we must go to other countries where emotions are better understood or better expressed for the *au revoir* or "*auf wiedersehen* that we all in our hearts desire to utter We hope that you who have come among us will on some future occasion once more cross the seas and I am sure on behalf of those who succeed me that you will on all other occasions experience the same hearty welcome which we have endeavoured to give you at the present time I must not sit down without making on behalf of our council my own and their own humble apologies for some of the shortcomings which may have taken place at our Congress My colleagues one and all have been fairly overpowered with work and if everything has not been as perfectly arranged as clockwork you will in the kindness of your hearts overlook our omissions and recognise that the will was there, however imperfect the performance Let me thank you not only for ourselves, but on behalf of our country and on behalf of the world for the magnificent array of scientific men of distinction who have accepted our efforts and come to help us in our councils It is with a feeling of pride that I find myself here addressing men whose names are household words in Europe and throughout the world We shall be able to look back to the time when we spoke to them face to face and in our humility we hope that they when they return home will not entirely have forgotten us We only wish our foreign guests what in the words of our American cousins we have tried to give them here—that is "a good time" We wish them all a fortunate journey home and trust that they may gather there further honours and that in time to come we may once more meet in the capital of our country when I am bound to say that we will give them the very heartiest reception that they have ever had. In saying farewell we wish our guests all possible good which may attend the happiness of man — The toast was responded to by Professor E G Janeway (America) Professor L R von Schrotter (Austria) Dr Martin (Belgium) Dr Mikailovsky (Bulgaria) Professor B Bang (Denmark) M Félix Voisin (France), Professor O Gerhardt (Germany) Professor Pel (Holland) Councillor Raiz (Hungary) Professor Cervello (Italy) Dr [illegible] zmo (Roumania) Señ[illegible] Dr Klas Linroth (Swe[illegible] and M Malm (Norway) M Voisin whose wonderful elocution allowed of his being understood though speaking in French all over the vast hall intimated that the President of the French Republic authorised him to invite the coöperation of those present in a similar Congress to be held in Paris in 1902 or 1903

The toast of Greater Britain' was in the absence of Sir James Crichton Browne, proposed by Sir Herbert Maxwell and was replied to by Surgeon General Harvey (India) Sir David Tennant and Sir John Cockburn

'The Health of the Chairman was given by Sir William S Church who said that they were all aware how admirably Lord Derby had presided over the Congress and over that banquet but they were not all equally aware of the debt that the Congress owed him since he had undertaken the presidency of the organising committee and of the council — The Chairman in reply dealt with the question of the desirability of establishing sanatoria for the poor and concluded with an acknowledgment of the services rendered by Mr Malcolm Morris and Dr StClair Thomson.

Correspondence.

"Audi alteram partem."

PROFESSOR KOCH'S ADDRESS AT THE BRITISH CONGRESS ON TUBERCULOSIS.

To the Editors of THE LANCET.

SIRS,—I desire to call attention to an apparent omission in that portion of Professor Koch's address in which he deals with the results of his experimental feeding of swine with bovine tuberculosis. The animals, he says, which "had eaten bacilli of bovine tuberculosis had without exception ...... tuberculous infiltration of the greatly enlarged lymphatic glands of the neck and of the mesenteric glands and also extensive tuberculosis of the lungs and spleen." But although the swine had been infected by the method of feeding no mention is made as to whether tuberculous lesions of the intestine were found in any of the experimental animals. This omission appears to be the more remarkable seeing that in discussing the reasons for his assumption that bovine tuberculosis cannot be conveyed to man by the ingestion of milk or butter containing "living and perfectly virulent bacilli" Professor Koch makes the definite assertion that it is "only when the intestine suffers first" that a case of tuberculosis can be assumed with certainty to have been "caused by alimenta." It may be that although in Professor Koch's address, as reproduced in THE LANCET, no mention of the fact is made, nevertheless, tuberculous lesions of the intestine were really present in addition to those which he enumerates, but in view of the importance which Professor Koch evidently attaches to this condition in the case of man the publication of full details of the post-mortem examinations of these pigs would be of considerable interest.

I am, Sirs, yours faithfully,

July 30th, 1901. S. MONCKTON COPEMAN.

THE SALE OF DRUGS BY MEDICAL GRADUATES.

To the Editors of THE LANCET.

SIRS,—I am instructed to send you the annexed copy of a resolution recently adopted by the Senatus Academicus of this University and to request that you will kindly give it a place in the next issue of THE LANCET.

I may mention that a similar resolution has been adopted by the University of Edinburgh.

I am, Sirs, yours faithfully,

DONALDSON ROSE THOM,

University of Aberdeen, July 29th, 1901. Secretary of Senatus.

(COPY.)

"Whilst it is admitted that the exigencies of practice in certain localities may sometimes render it unavoidable for a medical practitioner to supply to his patients the remedies which he prescribes—the Medical Faculty of this University is of opinion that it is undesirable and detrimental to the position of medical graduates of the University that this custom should be followed under other circumstances; and further, it regards the sale of objects other than remedies by its medical graduates as, under all circumstances, to be strongly deprecated"

THE HIGH ALTITUDE TREATMENT: A CORRECTION.

To the Editors of THE LANCET.

SIRS,—In reference to my paper read at Section II. of the Congress on Tuberculosis (on the Physiological Principles of High Altitude Treatment) the table of comparison of the results of different climates, which you have published in THE LANCET of July 27th, p. 239, is Dr. Theodore Williams's and not mine.—I am, Sirs, yours faithfully,

Dr. O. AMREIN (Arosa, Switzerland).

"THE PROPOSED LEGISLATION ON BAKEHOUSES."

To the Editors of THE LANCET.

SIRS,—The calm and rational tone of the annotation in THE LANCET of July 27th. p. 221, on the proposed legislation on bakehouses contrasts most emphatically and most favourably with the wild and whirling words which appear in the daily press on the subject. This is the first reflection that occurs to one in reading your remarks and the next is some regret that you should even appear to give the weight of your authority and influence to the proposal to abolish all underground bakehouses. A great many of these bakehouses are quite insanitary and their suppression is a consummation devoutly to be wished, but there are other underground bakehouses which are as perfect—from a sanitary point of view—as any above-ground bakehouses can be. And further—and this is perhaps still more important—there are a great many basements which might be occupied as bakehouses and could be made perfect models of sanitation. At present the fatuous clause in Mr. Asquith's Bill prohibiting the opening of any new underground bakehouse stands in the way, so that the occupiers of insanitary bakehouses are practically compelled to go on as they are. You are doubtless aware that some of the finest public buildings in London—such as the Queen's Hall and the Victoria suite at the Hotel Cecil—are underground in the sense that their floor is below the street level. The fact that it would be illegal to convert any of these places into a bakehouse is the *reductio ad absurdum* of the clause over which Mr. Asquith and Mr. John Burns are congratulating themselves.

Your proposal for a committee of experts is one which I advocated some time ago, and is the first step which an enlightened Government would take. Let such committee settle what is necessary for sanitation, and let the results of their working be taken as a basis for legislation; but do not let us impose upon the baking trade a restriction which is neither necessary nor desirable and condemn all underground bakehouses because some are worthy of condemnation.

I am, Sirs, yours faithfully,

EDITOR OF "THE BAKER AND CONFECTIONER."

July 29th, 1901.

ISOLATION HOSPITALS AND SCARLET FEVER.

To the Editors of THE LANCET.

SIRS,—There were so many who wished to speak in the discussion on this subject at Eastbourne on Friday, July 26th, that I held back, feeling sure that someone would take up three points which to me seem to demand consideration. As they were passed by with little or no notice perhaps you will allow me to state them briefly.

1. The more completely isolation is carried out in a given district, of any infectious disease liable to importation, the larger must be each year the number of children not protected by previous attacks and therefore liable to infection. No district has ever managed to isolate more than a part even of the notified cases, and there remain in addition to those known cases left at home all the unrecognised cases as well as the importations from other districts. Outbreaks of measles show what this involves.

2. Isolation, even if partial, is of great value to individual families, not only in enabling them to pursue their occupations with less interruption, but also because it enables them, if not to save their other members from the disease altogether, at any rate to postpone the age at which they take it and so to reduce the risk of mortality.

3. The experience of small-pox (and I probably might say of plague) shows that no serious epidemic of very infectious disease can be controlled by hospital isolation alone. At Middlesbrough, Glasgow, and I think at Gloucester, the spread of the disease was not really checked until general revaccination was introduced. Yet no one seems to question the value of isolation hospitals in small-pox, and I am convinced that in at least two cases, and probably five or six, outbreaks of that disease have been rendered harmless in my own neighbourhood by isolation hospitals. It is the mild and unrecognised cases that will always make complete isolation impossible and incomplete and inefficacious in stamping out small-pox. Why should we expect better results in the case of scarlet fever where as yet we have nothing like vaccination to help us? And is it wise to unsettle public opinion by expressing doubts of the value of isolation hospitals from one point of view without mentioning their advantages in other aspects?

I am, Sirs, yours faithfully,

MICHAEL THOMAS SADLER, M.D. Lond.,

Medical Officer of Health of Barnsley.

Barnsley, July 29th, 1901.

"THE TIMES ARE TROUBLOUS."

To the Editors of THE LANCET.

SIRS,—I can fully bear out your correspondent, "G. P.," in his reference (in his letter in THE LANCET of July 27th, page 229) to the out-patient department as far as my experience goes. Being one of those members of the profession who are devoid of capital I have held an appointment for nearly two years in a hospital and dispensary where the care of the out-patients is entirely in my own charge. The population of the town where this institution is situated is only 12,000, yet we receive an average of over 200 recommendations per month. Many of the patients are in a much better worldly position than myself. I am paid £100 a year or so to treat all comers; the majority are single men with wages of from £1 to 25s per week and married couples with from 25s. to £2. A not inconsiderable number have a much higher income, some owning businesses, horses, and fair house property, and in one instance a good farm of 90 acres. I "jibbed" at this a little at first, but was sharply pulled up by my committee. A rigid wage-limit should be fixed, in my opinion, as the practice of giving so much medicine and advice free, not to speak of attendance at home and luxuries provided by "charitable" people, only encourages thriftlessness and a habit of spending all surplus money in the small public-houses that infest every back lane in this and other towns. At the very least the home-visiting system should be kept within very narrow bounds as it is greatly abused. I am, Sirs, yours faithfully,

July, 1901. SWEATED.

WALES AND WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

The Gelligaer Medical Officer of Health.

THE sanitary district of Gelligaer is really the Merthyr rural district and is contiguous to the town of Merthyr. For many years the late Mr. T. J. Dyke acted as medical officer for Gelligaer and he held the same position in Merthyr. Upon Mr. Dyke's death last year Dr. W. W. Jones, who had been deputy medical officer of health for several years, was appointed medical officer of health for Gelligaer and retained his private practice in Merthyr. When the resolution formally to re-appoint Dr. Jones was before the district council on May 2nd last it was decided by a small majority to insist upon his residing within the area of the Gelligaer district. Dr. Jones having placed before the Local Government Board definite reasons against the proposal, and the district council having stated that they were following the example of the metropolitan boroughs, the Board sent a communication to the council pointing out that the metropolitan medical officers of health are required to devote their whole time to their duties and are paid fa[illegible] uncil propose to pay; and, furthe[illegible] nsist upon a medical officer of [illegible] strict there could be no combine[illegible] one official. There is no very definite centre in the district of Gelligaer which is made up of colliery villages with populations varying from 2000 to 3000 persons, and as each village has already its own colliery surgeon Dr. Jones would be deprived of his present private practice in Merthyr and the district would, in point of fact, obtain his whole services at the salary of a part-time medical officer of health.

Glamorgan Lunatic Asylum.

In his recently issued annual report the medical superintendent (Dr. H. T. Pringle) states that among the 485 patients who were admitted to the Glamorgan County Asylum at Bridgend during the year 1900 there were 13 who were under 15 years of age and several of these were almost infants. He suggests that a special idiot asylum should be established where these children could be cared for and trained to much greater advantage than when associated with adult lunatics whose language and conduct are not good examples for them. Dr. Pringle also urges upon the asylum committee the desirability of founding a benevolent fund for the assistance of those patients who return to their homes recovered but who, in the case of men, find it difficult for a time to secure employment. The county borough of Cardiff is entitled to 475 of the 1560 beds for which the Bridgend Asylum has accommodation. It is not anticipated that the asylum to be erected at Whitchurch, for which plans are now being prepared for the Cardiff corporation, will be ready for occupation before the end of 1904, and in the meantime patients are being sent from Cardiff to Carmarthen, Hereford, *and other places owing to the lack of accommodation at* Bridgend.

Delegates to the British Congress on Tuberculosis

If the interest which is taken in the public health service by the sanitary authorities of Wales is to be measured by the number of delegates who were appointed to the British Congress on Tuberculosis the principality must be in a bad condition. The University of Wales elected four delegates, but there was no representative from a single Welsh county council, not even excepting Glamorgan or Monmouthshire, and among the large towns, Cardiff, Swansea, and Newport alone sent delegates, while of rural districts that of Llandaff and Dinas Powis was the only one represented.

Cardiff Sanatorium.

It has hitherto been the custom for the Cardiff Corporation to treat all patients at the sanatorium free of charge with the exception of those cases sent in by the board of guardians The Health Committee has now decided to make no charge to the board when the patient sent in by a Poor-law medical officer is merely in receipt of medical relief, but when receiving such relief as to constitute him a pauper a charge of 6s. per week will be made to the board.

Dr. Thomas Young.

A portrait of Dr. Thomas Young, from the painting by Sir Thomas Lawrence, has been placed in the Victoria Hall, Milverton, Somerset, with the following inscription: "Thomas Young, M.D., F.R.S., &c, born at Milverton 1773, died 1829, physician, natural philosopher, and master of many languages. He first established the undulatory theory of light, and translated the Rosetta Stone, which is the key to our understanding of the Egyptian hieroglyphics."

July 29th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

University of Aberdeen.

AMONG those who were "capped" at the summer graduation ceremony were 28 candidates who had passed the final examination in the medical faculty.—At the last meeting of the university court gifts of human skulls, &c., to the university museum, from Professor R. W. Reid (Professor of Anatomy in Aberdeen University) and Mr. Ian Rose, medical officer of the Uganda Railway Company, were intimated. Additional examiners for degrees in medicine, &c, were also appointed.—Lord Strathcona is to [illegible] £25 000 to the University Extension [illegible] balance required (£20,000) being [illegible] Of this latter sum £2000 has already been promised and the special committee are forthwith to issue an appeal for subscription of the £18,000 still wanted. At the graduation ceremony above mentioned eight medical practitioners were promoted by examination to the degree of M.D. and the honorary degree of LL.D. was conferred on Surgeon-Major Alfred William Alcock, I.M.S., Professor of Zoology in the Medical College of Calcutta, and Professor Rudolph Virchow, Berlin.

July 30th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Belfast Water Board.

AT the present time anything but cordial relations exist between the Belfast Water Commissioners and the Public Health Committee in reference to the origin of the epidemic of typhoid fever The matter is being a good deal discussed at present from the fact that in a pending vacancy at the Water Board one of the candidates, who is also a medical man (Dr. John Barron), believes that the cause of the frequent—I may say, almost annual—outbreaks of typhoid fever in Belfast is to be found in the polluted subsoil, the result of defective drainage. Dr. Barron says that if he is elected to the Water Board he will retire from the City Corporation.

Sanatoria for the Poor.

Mr. Robert Hall, medical attendant at the Belfast Union Hospital, has recommended the guardians to build a sanatorium in the county for their numerous tuberculous patients, but they have declined on the ground that the poor rates could not be devoted to such a purpose.

Medico-Psychological Association of Great Britain and Ireland.

The sixteenth annual meeting of the above association was held in the Queen's College, Cork, on July 25th and 26th. At the commencement of the proceedings the chair was occupied by Dr. Fletcher Beach, the out-going President, who introduced the President for the coming year, Dr. Oscar T. Woods, medical superintendent of the Eglinton Asylum, Cork. Dr. Woods in the course of his presidential address pointed out that the first public attempt to provide for the treatment of the insane poor in Ireland was made in the year 1728, and he gave an interesting history of the progressive improvements in the treatment of insanity. Between 60 and 70 members attended the meetings and some valuable papers were read. On July 25th the President gave a banquet to the members and several friends at the Imperial Hotel. On the following day Dr. and Mrs. Woods were "At Home" and a large number of guests assembled in the charming grounds of the Eglinton Asylum.

July 30th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Institute of Colonial Medicine.

THE competition which I have already referred to in one of my previous letters[1] between the various towns as to which should have the honour of organising an official course of instruction in colonial medicine still continues. The partisans of this school being created in Paris have collected a sum of money which although considerable is nevertheless insufficient unless Government grants come to their aid—an event which is exceedingly improbable. The Minister concerned with the affair has decided that the instruction shall be given at Bordeaux where the local faculty has already created the organisations necessary and has founded a special diploma in colonial medicine. On the other hand, there is Marseilles to be considered. This city is the port of departure of all the French steamship lines in connexion with the great colonies and receives annually from the colonies on an average 1300 military and naval invalids and 600 civilian invalids. Marseilles offers a magnificent field for study and the clinique has a perfect installation far superior to that which might have been arranged in Paris. Since 1899 the municipal council has created at the School of Medicine five new chairs, one in the bacteriology and pathology of foreign countries, one in colonial hygiene, climatology, and epidemiology, one in colonial natural history, one in tropical clinical medicine, and one in colonial materia medica and bromatology. The professors holding these chairs deliver lectures in colonial medicine to doctors of medicine who reside for three months in the school and who have a special examination which comprises a written paper, for which four hours are allowed, dealing with the pathology of tropical diseases, the hygiene of hot countries, and sanitary police matters. There are also a *virâ voce* examination in tropical medicine and practical examinations in microbiology, in the laboratory diagnosis of tropical diseases, in parasitology, and in anthropology and urology as far as they deal with points in tropical pathology. Marseilles also possesses in addition to the School of Colonial Medicine a general colonial department organised at the expense of the Chamber of Commerce under Professor Henkel. This has about 200 students and seven special chairs dealing with the following subjects: vegetable and animal products, parasitic diseases of plants, mineral products, physical geography and geology of the colonies, colonial hygiene and commerce, colonial economics, jurisprudence, and agriculture.

The Chair of Ophthalmology of the Faculty of Medicine.

The faculty has just nominated by election a new professor of ophthalmology to replace M. Panas who has handed in his resignation. The election has given rise to a great deal of discussion. It is always the custom to choose the professors of the faculty of medicine of Paris among those medical men who have been nominated as *agrégés* at a former competition. The only exception to this course is at the creation of a new chair, which is very rare, and even then it is almost always an *agrégé* who is chosen to fill it. In the present case among the *agrégés* of the faculty of Paris there was only one medical man practising as an ophthalmic surgeon, and he could have been chosen as successor to M. Panas, but the professors of the faculty saw that with one candidate there was no opportunity of making a selection, and so they admitted various *agrégés* and professors from the provincial faculties as candidates—amongst others M. Lagrange of Bordeaux and Professor de Lapersonne of Lille. The generality of medical men in Paris and the press were anxious that the faculty should be still more liberal and should allow the candidature of some of the Paris ophthalmologists, several of whom are not *agrégés* of the faculty, a circumstance which is explained by the fact that the chair of ophthalmology which was occupied by M. Panas was a comparatively new creation and that at the age when the Paris ophthalmic surgeons begin their career as specialists they have no particular interest to present themselves for examination as *agrégés*. Throwing open the competition to men of distinction would have been a very popular measure, but the faculty preferred to maintain its ancient traditions and after a severe contest appointed the professor from Lille, passing over the Paris *agrégé* and the Paris medical men who are not *agrégés*.

Prevention of Ophthalmia Neonatorum.

Whilst certain legislative measures relative to public health were being discussed in the Senate a senator who was also a medical man proposed the introduction of a clause making it compulsory for midwives and accoucheurs to bathe a new-born child's eyes at once with solution of permanganate of potassium in order to prevent ophthalmia. The Minister of the Interior consequently requested the Academy of Medicine to supply him with an outline of the instructions which ought to be given to midwives in this respect. M. Pinard, to whom the question was referred, was of opinion that permanganate of potassium ought not to be ordered specially and exclusively, as it is by no means the only substance efficacious in the treatment of ophthalmia. The recommendations of M. Pinard were as follows: (1) the distribution in all *mairies* of short descriptions of the causes, symptoms, and dangers of ophthalmia in new-born infants; (2) immediate notification of purulent ophthalmia everywhere and in all cases; and (3) the appointment in connexion with lying-in establishments (clinics and maternities) of ophthalmologists to superintend the treatment of purulent ophthalmia and to give the requisite instructions to the pupils, medical men, and midwives.

July 29th.

THE SERVICES.

ROYAL ARMY MEDICAL CORPS.

SURGEON-CAPTAIN A. MACDONALD, Army Medical Reserve, assumes temporary medical charge of the troops, Station Hospital, Edinburgh Castle. Captain C. Dalton, at Hounslow, is ordered to West Africa for service. Surgeon-Major Crooke-Lawless joins at Aldershot for duty. Lieutenant J. B. Clarke has joined at Aldershot, and has been posted to the Depôt for a course of instruction. Lieutenant-Colonel M. D. O'Connell is appointed principal medical officer, North-Eastern District, vice Colonel W. E. Saunders, posted to India.

IMPERIAL YEOMANRY.

18th Battalion: The under-mentioned officer relinquishes his commission, dated July 16th, 1901: Temporary Captain H. W. Whyte, Medical Officer.

SOUTH AFRICAN WAR NOTES.

Civil Surgeons Tucker, John Burton Rudduck, and Davies have been discharged from hospital for duty. Civil Surgeon C. R. Hodgson is on passage home.

Garrison Artillery). George Johnston to be Surgeon Lieutenant. Dated July 27th 1901. *Rifle*: 2nd (Prince of Wales's) Volunteer Battalion the Devonshire Regiment: Surgeon-Lieutenant A. R Rendle to be Surgeon Captain. Dated July 27th, 1901. 1st Volunteer Battalion Princess Charlotte of Wales's (Royal Berkshire Regiment): Surgeon-Lieutenant W. G. Heasman to be Surgeon Captain. Dated July 27th, 1901.

His Majesty the King held an Investiture at St. James's Palace on July 25th and conferred the Distinguished Service Order upon the following officers:—Surgeon Captain W. Fletcher and Staff Surgeon E. C. Lomas, R.N.

Major R. P. Bond, R.A.M.C., was amongst the recipients of war medals presented by the King at Marlborough House on July 29th.

Surgeon Major General W. A. Thomson, A.M.S. (retired), Honorary Physician to the King, has been selected for a Good Service Pension of £100 a year.

Obituary.

CARSTEN HOLTHOUSE, F.R.C.S. ENG., L.S.A.

MR. CARSTEN HOLTHOUSE had truly reached a ripe old age when almost at the end of his ninety-first year he closed his earthly career on July 18th. He was little known to the present generation of the profession, but 30 years ago, as senior surgeon to the Westminster Hospital and lecturer on surgery in its school and as a frequent attendant at the medical societies, he was a familiar figure. There are many who will remember the short, spare, well-set man, brisk in his movements, somewhat brusque and dogmatic in the enunciation of his own views, yet always kindly and conscientious in his criticism of the opinions of others, and keen and enthusiastic in the interest he ever took in surgical practice and in the progress of surgical knowledge. His enthusiasm and absence of self-seeking were notable and could not fail to gain for him the respect and esteem of his contemporaries.

Mr. Holthouse was born on Oct. 14th, 1810, at Edmonton, being the eldest son of Mr. Carsten Holthouse of that place. After an education at private schools he in his fifteenth year, became the articled pupil, as was then the custom, of his uncle, Mr. Le Gay Browerton of Bawtry, in Yorkshire. Later he entered at St. Bartholomew's Hospital and was a dresser under the late Sir William Lawrence. As was usual at that time he sought the double qualification and became a Licentiate of the Society of Apothecaries in 1832 and a Member of the Royal College of Surgeons of England in 1833. After a visit of some six months to the Paris hospitals he commenced practice in his father's house in Keppel-street and industriously attended the out-patient department of St. Bartholomew's Hospital. We next hear of him as being appointed lecturer on anatomy and physiology at the Aldersgate-street School of Medicine in succession to, and at the instigation of, Mr. Skey. It was whilst holding this appointment that Mr. Holthouse became known as a teacher and made a reputation which led to his election as one of the original Fellows of the College in 1843. At the time of his death he was the senior of the very few surviving original Fellows.

In 1849 Mr. Holthouse was the successful candidate for the Lectureship of Anatomy of the resuscitated Medical School of Westminster Hospital. His valuable services on taking up this appointment were very inadequately appreciated at the time. Dr. Hunter, his predecessor in the chair, had a few years before carried away with him the greater part of the anatomical preparations, probably his own private property, and a month after Mr. Holthouse had begun his first course of lectures the College of Surgeons condemned the deficient remains of the anatomical museum as insufficient for the proper teaching of the subject, and the school would have been closed had not Mr. Lane of the Grosvenor-place School offered to take over the anatomical pupils. Mr. Holthouse at the same time undertook, if £30 were granted to him for the purpose, to provide before the end of the year all the anatomical preparations required by the College. He was at once appointed curator of the museum, the amount was voted, and before the end of December, by making good every one of the deficiencies, he satisfied the requirements of the College authorities and obtained permission for the students to resume their attendance at his anatomical lectures. The school, however, did not prosper, and after lecturing for five years without remuneration Mr. Holthouse was so dissatisfied with the condition and management of the school that he sent in his resignation of the chair of Anatomy. This brought matters to a head, and Mr. Holthouse was induced to continue to hold his chair by being unanimously appointed sole manager of the school with a free hand to make the necessary improvements. In this way Mr. Holthouse saved the school from destruction and was the energetic means of establishing it on a more satisfactory basis. Mr. Holthouse was appointed assistant surgeon to the Westminster Hospital in April, 1853. In the following year, a base hospital for the sick and wounded from the Crimean war having been established at Smyrna, he went out as one of its surgeons in company with Hulke and Streatfeild and others. On his return to London he took a house at Storey's-gate and resumed his work at Westminster. At the same time he took up the study of ophthalmic surgery and soon after assisted in the founding of the South London Ophthalmic Hospital, an institution which has recently been rebuilt and has discarded all local association from its name. In 1857 he was promoted to the full surgeoncy of Westminster Hospital, a post which he held until 1875, when by the rules of the hospital he retired to the office of consulting surgeon. For some years, too, he held the chair of Surgery in the school, a post from which he retired in 1873.

Mr. Holthouse's published writings show best the versatility of his mind. In 1838 he wrote three papers on the "Acarus Scabiei" which attracted some attention. In 1854 he published "Six Lectures on the Pathology of Strabismus and its Treatment by Operation." Four years later appeared a book on "*Squinting, Paralytic Affections* of the Eye, and Certain Forms of Impaired Vision." In the same year, in 1858, he published "Practical Observations on the Radical Cure of Inguinal Hernia." In 1870 he gave to the profession his more mature views on this subject in a larger volume "On Hernial and other Tumours of the Groin and its Neighbourhood, with Practical Remarks on the Radical Cure of Ruptures." The article on the lower extremities in the second volume of Holmes's "System of Surgery," which appeared in 1870, was from his pen. A year later he published a *brochure* "On the Proper Selection and Scientific Application of Trusses." After his retirement he took great interest in the question of the treatment of inebriates and wrote letters and articles on the subject which conduced much to a more healthy public opinion on the subject.

Mr. Holthouse possessed a sound practical knowledge of surgery and was in many ways a good teacher. If he failed to make his mark as a successful competitor for the confidence of the public it was probably the natural result of the versatility of his mind on the one hand and of a certain want of concentration on the other. As has been well said, success would seem to be almost impossible without a power of concentration and a habit of attention to minute details and it was doubtless owing to defects of this kind that Mr. Holthouse failed to secure the public appreciation which his talents deserved. Mr. Holthouse was twice married—in 1853 to Agnes, the daughter of Mr. Samuel Kent of Clifton, and in 1869 to Martha, daughter of Dr. John Inglis Nicol of Inverness. Of his children by his first wife three sons survive him.

THOMAS LIVINGSTONE, M.D., M.S. GLASG.

DR. LIVINGSTONE passed away at London on July 16th at the age of 52 years on his return from Germany where he had been staying for the benefit of his health. For the last two years he had been suffering from angina pectoris and on the recommendation of his medical advisers he went seven weeks ago to Bad-Nauheim for the Schott treatment. His health, however, did not benefit from the visit and it was on his way home to Stanhope, Co. Durham, that he suddenly expired at a London hotel. The deceased gentleman had acquired a large practice at Stanhope. Not only did he gain distinction by his medical and surgical skill but by his kindness and geniality he became not only the medical adviser but the friend and counsellor of all classes, but more especially of the poor and needy. He also interested himself in local affairs and at various periods of his life held all the important local public offices. He became a member of the Stanhope School Board at its formation, and for the last 23 years, until his untimely death, was its chairman. He also took an active part in Poor-law affairs, and he became a member of the board of guardians, being chairman from April, 1885, to February, 1894, when he resigned. For some years he was medical officer of health of one of the Stanhope rural districts. In educational matters he took a very deep interest. The best instruction that was obtainable he wished to place at the disposal of the people, and it was chiefly due to his efforts that the School Board, finding that small wages were unproductive of good results, decided to remunerate their teachers more liberally. On the establishment of the county councils Dr. Livingstone was elected a member of the Durham county authority. His services in connexion therewith were highly valued and he was elected an alderman eight years ago, which position he held at the time of his death. He was also chairman of the Health Committee of the county council and had occupied that position for the last 10 years with great ability. He took a very lively interest in the St. John Ambulance Association and in the volunteer forces he occupied the position of surgeon for many years. He was also a magistrate for the county of Durham, being appointed some 10 years ago. As evidence of the esteem in which the late Dr. Livingstone was held by his friends and neighbours of Stanhope and the dales two years ago he received a handsome presentation, the outcome of public subscription, on the occasion of his silver wedding. His funeral, which took place on July 18th, was largely attended, genuine sorrow being evinced by all classes. He leaves a widow (a sister of Mr. Joseph Walton, M.P.) and two sons to mourn their loss.

CHARLES DAGNALL CLARK, M.B. LOND., M.R.C.S. ENG., L.R.C.P. LOND.

THE death is announced, at the early age of 45 years, at Sydney, N.S.W., of Dr. C. D. Clark, eldest son of the late Mr. Alfred Clark, Cross Deep, Twickenham. He was educated at Uppingham, and on leaving that school decided on entering the medical profession. He matriculated at the University of London, first in honours with scholarship. As a student of St. Bartholomew's Hospital, London, he obtained the Kirkes gold medal and was appointed resident gynæcologist under Dr. Matthews Duncan. His health failing he left for Australia, where he shortly afterwards obtained the appointment of resident surgeon at the Prince Alfred Hospital, Sydney. After three years' service he entered upon private practice and was appointed on the staff of the hospital. His death will be mourned by a large circle of patients and friends. He leaves a widow and four children.

"SALTPETRE."—At the Devizes Borough Petty Sessions held on July 18th, a firm of provision merchants were summoned at the instance of the Wilts County Council for selling as saltpetre an article which was not of the quality and substance demanded. The county analyst stated that the percentage composition of the sample sent to him as saltpetre consisted of sodium nitrate, 97·2 per cent; potassium nitrate, 1·8 per cent.; chlorides and sulphates, 0·7 per cent.; and water and insoluble matter, 0·3 per cent. For the defence it was stated that hundreds of tons of this substance were sold for bacon-curing purposes. The magistrate inflicted a fine of 10*s.* in addition to 8*s.* 6*d.* costs.

CARMARTHEN JOINT COUNTIES LUNATIC ASYLUM.—The thirty-sixth annual report of this asylum, which accommodates the lunatics of the three counties of Carmarthen, Cardigan, and Pembroke, has just been issued. During the year 116 cases (67 males and 49 females) were admitted. The discharges amounted to 57. The deaths numbered 76, a larger number than usual owing to an outbreak of influenza On Dec. 31st, 1900, there remained under treatment 633 patients (329 males and 304 females). The charge made for maintenance of pauper lunatics was 7*s.* 7*d.* per patient weekly.—Miss Alice Neville Johnson, M.D. Brux., L R.C.P. Edin., L.S.A., was appointed on July 25th second assistant medical officer to the asylum at a salary of £130 per annum.

THE BRITISH MEDICAL ASSOCIATION.

MEETING AT CHELTENHAM.

THE sixty-ninth annual meeting of the British Medical Association commenced its session in Cheltenham on Tuesday, July 30th. This is the second time that the Association has visited Cheltenham, the first being in 1837, the year of the accession of Her Majesty Queen Victoria, and it is somewhat curious that the year of the present visit is marked by the accession of His Majesty King Edward VII.

Dr. G. B. Ferguson, President of the British Medical Association, delivered an exceedingly interesting Presidential Address at the first (adjourned) general meeting. His description of the position now occupied by scientific medicine was not only eloquent but learned. As a rule a *résumé* of medical progress is rather a dreary thing to listen to, the orators who are condemned by circumstances to speak to this theme being apt to use the same words in describing the same things. Dr. Ferguson's address was not in the least stereotyped in character. Obviously familiar with the many-sided developments that have followed upon recent research, he touched suggestively upon the more important, and in so doing justified his forcible plea for better facilities in this country for the pursuit of science. "A Faraday, a Koch, a Pasteur would be a cheap purchase at a million" is his forcible answer to those who would oppose the educational demands of progressive science by a counter-cry of economy.

Cheltenham is of course renowned for its waters, its good shops, its tree-bordered streets, and its educational advantages for either sex.

The town has evidently decided to "do the thing well," and even the shops show the influence of medicine. Thus the principal printshop has filled its windows with medical pictures. There is a photograph of Rembrandt's celebrated "Lesson in Anatomy," and engravings of Luke Fildes's "The Doctor," and William Small's "The Good Samaritan" This last-named picture, which attracted some notice in the Academy last year, illustrates an episode in the day of a country practitioner with great fidelity. The child of a gipsy has been taken ill and the dogcart of the medical man has been stopped as he passes the encampment. There are also in this shop four studies of apparently quite healthy young women stripped to the waist and entitled "L'Odalisque," "Epanouissement," "Jeunesse," and "Reverie," chosen, we suppose, to exhibit different types of chest.

The opening service was held at St. Matthew's Church on Tuesday, July 30th, at 11.30 A.M., when the large congregation completely filled the building. The preacher was the Very Rev. the Dean of Gloucester (Dr. Spence), who based his remarks upon the text, "Luke, the Physician," and, in concluding, paid a warm tribute to the work done by the medical profession which, in his opinion, most nearly approached to the ideal of the Master Himself. The musical portion of the service was of a very mediocre description and slovenly in parts—probably due to an augmented choir which had not practised together. The collection, as usual, was on behalf of the Royal Medical Benevolent College and the British Medical Benevolent Fund.

The Organising Committee of Reception and certain of the municipal authorities, with whom was the mayor, gave their first welcome and "at home" to the members and their friends in the Winter Garden of the "Garden Town," on Monday evening, July 29th, thereby pleasantly anticipating the opening of the meeting. The Winter Garden, which is a large glass structure of pleasing ornamental design, was gaily decorated and the illuminated fountains in the centre served to relieve the closeness of the atmosphere. The lawns were illuminated with myriads of fairy lights. The guests were well pleased with their reception and with the excellent entertainment provided, which exceeded in display and magnitude any similar event of previous occasions.

The fact is, Cheltenham is admirably adapted for both the festive and the serious side of a gathering of this sort. There are excellent buildings wherein to hold the meetings and open spaces for garden parties. Above all, the various places of meeting and of entertainment are not scattered, but within an easy distance of the reception room and Winter Garden.

Not the last to appreciate the excellent accommodation which Cheltenham affords were the exhibitors in the Annual Museum. No better place could have been selected than the Winter Garden, and the exhibitors themselves did not miss their chance of making their exhibits attractive. It need hardly be added that the fact that the first reception was held in the Winter Garden and on its lawns was very much appreciated by the exhibitors. Everyone's attention was thus necessarily drawn to the exhibits and the building was crowded even up to the time of closing —11 P.M. The genial weather added considerably to the pleasure of the occasion. We deal at length elsewhere with the great number of exhibits comprising drugs, foods, and medical and surgical appliances that were presented to view. An important feature of the exhibition this year was the display of ambulance wagons, motor-cars, &c., in a marquee on the grass adjoining the Winter Garden.

The general impression is that no previous exhibition has had such opportunities for securing success. The Pathological Museum (opened only to medical men) adjoined the Winter Garden. We congratulate the local organising secretaries on the very excellent way in which they have provided for, and dealt with, this important section of the meeting. They must certainly feel it a reward to hear on all sides expressions of pleasure and satisfaction with the arrangements.

Cheltenham is evidently keenly alive to the public health requirements as well as to general public administration. The water-supply is good and is derived from the huge watershed of the Cotswolds. But a reservoir situated a few miles up the Oxford and London road seems to us open to criticism. It is close to the road and apparently no provision is made to prevent road-dirt from getting into the water. The reservoir is not banked up, nor is it protected by a cordon of trees as is the case in most other places. The water is filtered. Cheltenham possesses a refuse destructor and a public abattoir. The sewage is discharged upon the land, though we should think that Cheltenham was favourably environed for a system of purification and disposal by bacterial methods. The public health is good, the vital statistics being very favourable. The electric light and the principal baths are in the administration of the corporation.

The waters of Cheltenham have, of course, been known from very early times, and it seems to us that they present a very interesting composition which deserves more attention than has hitherto been allotted to them. At the Montpellier Spa there are two distinct waters—one a magnesia saline water and the other an alkaline saline water. They may be regarded as mild Carlsbad waters, and there is no reason why they should not be just as therapeutically efficient, having regard to the amount of saline ingredients contained in them. At the Cambray Spa there are two waters—one a chalybeate and the other a saline. The chalybeate contains as much as seven grains of carbonate of iron per gallon, which are associated, it is interesting from a therapeutic point of view to add, with 24 grains of the purgative salt, sodium sulphate, and with sodium chloride. This spa is not under the management of the corporation.

In the prettily wooded and watered Pittville Park, to the north-east of the town, is situated the Pittville Spa and Pump-room. The water here belongs to the class of alkaline saline waters. The sulphated waters are concentrated by evaporation for convenience of dosage. The Pittville Spa contains a spacious room for the amusement and recreation of people drinking the waters. All three sources of water are practically in a straight line from the south-west to the north-east of the town and nearly parallel with the tree-bordered promenade, the Montpellier Spa coming first, then the Cambray Chalybeate, and lastly the Pittville Spa.

The seventieth annual meeting of the Association will be held in Manchester next year, under the presidency of Mr. Walter Whitehead, F.R.C.S. Edin.

THE GENERAL MEETINGS.

THE FIRST GENERAL MEETING.

The first general meeting of the Association was held in the Princess Hall of the Ladies' College at 2.30 P.M. on Tuesday, July 30th. Both the members of the Council and the ordinary members of the Association were present in large numbers.

The minutes of the last annual meeting were, on the motion of Dr. W. A. ELLISTON, the retiring President, confirmed and adopted, after which Dr. Elliston vacated the chair in favour of his successor, Dr. G. B. Ferguson, senior surgeon to the Cheltenham Hospital.

Dr. FERGUSON, after thanking the Association for electing him, gave notice that he would move that a humble and loyal address should be presented to His Majesty King Edward VII., Patron of the British Medical Association. Having read the address it was duly seconded by Dr. JOHN ROBERTS THOMSON and carried unanimously.

The usual vote of thanks to the retiring President was then moved by Dr. M. BEVERLEY and seconded by Mr. VICTOR HORSLEY. This was unanimously carried and acknowledged in a few suitable words by Dr. ELLISTON.

The PRESIDENT (Dr. Ferguson) then reported the following recommendation:—

That the thanks of the Associa
Walter Hume Long, P.C., M.P.,
hydrophobia whilst President of

This was seconded by Mr. C. H. W. PARKINSON and carried unanimously.

The next business on the programme was the report of the Council and the financial statement, which was moved by Dr. ROBERTS THOMSON. He paid a tribute of sympathy to Mr. Fowke, the general secretary, in a few well-chosen words and also referred to the circumstances surrounding the family of the late Mr R B Anderson.

Dr. JOHN HADDON (Hawick) made his usual protest against the scientific grants, while Dr. BRASSEY BRIERLEY wanted to know about editorial expenses and the cost of printing

Mr. ANDREW CLARK, the treasurer, set Dr. Brassey Brierley's mind at rest about the cost of printing, after which Mr. COLIN CAMPBELL spoke as to the desirability of articles in the *British Medical Journal* being signed.

Dr. DAWSON WILLIAMS, the Editor of the *British Medical Journal*, then gave a few details as to how payment for articles in the journal was managed.

Dr HADDON, who had in his previous speech suggested that a scientific grant should only be allotted to research in some set subject, now handed in the following motion, which was seconded by Mr. NELSON HARDY :—

That it be a suggestion to the Scientific Grants Committee to offer the money they spend for a prize or prizes on some subject on which we require original research, such as metabolism.

After some remarks from Mr. BUTLIN, Dr. EDRIDGE-GREEN, and Surgeon-Colonel INCE, who was understood to move the previous question, Dr. Haddon was asked to withdraw his motion, but he refused.

It was accordingly put to the meeting and was lost.

The motion as to the report proposed by Dr. ROBERTS THOMSON and seconded by Mr. ANDREW CLARK was then put and carried.

It was in the following terms :—

That the report of Council, together with the financial statement for the year ending Dec. 31st, 1900, be received and adopted.

That Messrs. Price, Waterhouse, and Co. be, and they are hereby, appointed auditors of the British Medical Association until the next annual general meeting at a remuneration of £105.

The reports of the various committees were then received, but over the report of the Indian Military Medical Services Sub-committee a long discussion arose.

The report was as follows :—

REPORT OF THE INDIAN MILITARY MEDICAL SERVICES SUB COMMITTEE.

This Committee has met twice to consider the subject referred to it from the annual meeting held at Ipswich. The Committee has received a letter from Surgeon-General Harvey repudiating the charges put forth by Dr. Mullick against the I.M.S. The Committee has requested Dr. Mullick to furnish it with a summary of his evidence in support of his statements, but he has failed to communicate with the Committee in any way. The Committee deprecates the attitude of Dr. Mullick in preferring charges against the administration of an important public service which he has failed to substantiate.

JAMES BARR, M.D., Chairman.

Dr. SARAT K. MULLICK moved that the report be referred back. He had been granted a term of three months from April 30th within which to procure evidence. That term had not yet run out and moreover he had supplied the Committee with evidence by July 15th. Moreover, Dr. Barr had published in the *British Medical Journal* evidence which Dr. Mullick had supplied to the Committee and which was confidential.

Mr. GEORGE BROWN seconded.

Surgeon-General HARVEY reiterated his statements repudiating Dr. Mullick's charges, after which Mr. JOSIAH OLDFIELD, speaking as a barrister, exhorted the meeting to refer the report back because of the time-limit not having expired when the report was drawn up and because Dr. Barr had published evidence.

Dr. JAMES BARR, who was imperfectly heard in the body of the hall, was understood to point out that Dr. Mullick had produced no fresh evidence, but only that which had been already put in by the late Dr. Bahadurji.

Eventually a motion to refer the report back and another to leave out a portion of the report were negatived and the report was received.

The discussion of the Constitution Committee's report was deferred and the meeting adjourned.

THE (ADJOURNED) FIRST GENERAL MEETING.

The adjourned meeting was held on Tuesday evening in the Princess Hall of the Ladies' College, for the delivery of Dr. G. B Ferguson's presidential address. The attendance was good and among those present were His Worship the Mayor and many prominent citizens.

Mr. Alderman G. NORMAN presided.

The Local Secretary (Mr. G. A. CARDEW) read out the names of the foreign and colonial delegates, each of whom went on the platform and was welcomed by the President. Their names are as follows :—Dr. Durier, Dr. J. Rivière, Dr. Dubreuith, Dr. Sabouraud, and Dr. Noiré, of Paris ; Dr. Ernest Otto, of Teneriffe ; Dr. F. W. McRae, Dr. A. H. Ferguson, Dr. A. R. Reynolds, Dr. Punton, Dr. Allan Fisher, Dr. Lewis Schooler, Dr. B. T. Whitmore, Dr. J. C. Shruder, Dr. G. Dock, Dr. H. M. King, Dr. Emerson M. Sutton, and Dr. Judson Dorland, of the United States of America ; Dr. Boxhill, Dr. Gooding, and Dr. Wolseley, of the Barbadoes Branch ; Mr. Eldon Harvey, of the Bermuda Branch ; Dr. A. J. Turner, of the Brisbane and Queensland Branch ; Dr. W. H. De Silva, of the Colombo and Ceylon Branch ; Dr. G. P. Jordan, of the Hong-Kong Branch ; Dr. W. Young, of the New Zealand Branch ; Dr. W. Chisholm, Dr. W. H. Coutie, and Dr. E. M. Pain, of the Sydney and New South Wales Branch.

The MAYOR then addressed the meeting, commencing by saying that Dr. Ferguson needed no introduction. He then, in the name of the town, bade the Association welcome and called upon Dr. Ferguson to give his address.

The PRESIDENT, wearing the scarlet and crimson gown of his degree, then delivered his presidential address, which was as follows.

THE PRESIDENT'S ADDRESS.

[Dr. Ferguson took as the title of his address, "Scientific Research : the Indispensable Basis of all Medical and Material Progress," and commenced by bidding the Association welcome to Cheltenham. He referred to the fact that the Association had not visited Cheltenham since 1837, the year of the accession of their late lamented Queen, and that the year of their present visit was also the year of the accession of a British Sovereign, His Most Gracious Majesty Edward VII. He then passed on to give a short account of Cheltenham and its waters and mentioned several of the past medical worthies of the place. Such were Dr. Baron, Dr. Wyldbore Rumsey, Mr. Clement Hawkins, Mr. Charles Fowler, and Dr. Evans of Gloucester. He continued by reminding his hearers that the tripod of medicine was anatomy, physiology, and pathology. He then gave a *résumé* of the condition of medicine in Britain and other countries 100 years ago and in reference to Jenner spoke as follows :]

Dr. Edward Jenner.

A hundred years ago Edward Jenner was practising in Cheltenham, and here the *genius loci* reminds me that I must not dismiss our greatest medical celebrity with a single line. To me the most interesting point about Jenner is that he was educated by John Hunter, which is to say that he became and remained a naturalist. He was not, however, neglectful of medicine—indeed, he manufactured an improved tartar emetic—but he was at first more interested in fossils, hedgehogs, and cuckoos. His celebrated paper on the cuckoo, describing for the first time the inconsiderate conduct of the young cuckoo to his fellow-nestlings, need not be referred to here further than to state that for a long while he reckoned a personal visit to all the young cuckoos in his neighbourhood as the first of his or his nephew's duties in May and June. It was this kind of training in natural observation which led at last to such productive fruit as his celebrated Inquiry into the Causes and Effects of the Variolæ Vaccinæ, which was published in 1798. Wishing to test a tradition at Berkeley, where he was born and practised at first, as to the small-pox immunity conferred by cow and swine-pox, and fulfilling Hunter's injunction, "Don't think, but try," he made his first experimental inoculation from swine-pox on his eldest son, aged one and a half years, in November, 1789. It was nearly eight years afterwards before the next step was made, for it was on May 14th, 1796 (two years before the publication of his book), that lymph was taken from the hand of Sarah Nelmes of Berkeley, who had been infected by her master's cows and was inoculated into the arms of James Phipps, a healthy boy, eight years of age. A typical vesicle and areola were produced and two subsequent attempts to inoculate James Phipps with small-pox proved perfectly futile. Jenner next sent lymph to London to Mr. Cline whose patient also resisted all attempts to inoculate him with small-pox. Jenner was thereupon invited to London and wrote from Cheltenham in reply on Sept. 29th, 1798, his often-quoted letter in which he expresses his preference for the "lowly and sequestered paths of life, the valley and not the mountain," declaring his contentment and contempt of fame and fortune, "fame being only a gilded butt, for ever pierced by the arrows of malignancy." He took up his regular abode in Cheltenham in July, 1800. living at first in the High-street and aftewards at 8. St George's-place. Though often absent he spent much of his time here for many years, as letters of his dating from 1802 to 1813 testify, vaccinating gratuitously at Alpha House, Bayshill, the residence of the present Mayor of Cheltenham, all the poor who made application to him You know the rest, the rapid extension of the practice the world over, the parliamentary grants to him of £30,000, his medals and diplomas and honours from every nation, and the tardy and unwilling acceptance of his teaching by his own countrymen. Later came detraction, obloquy, and neglect, followed at last by 443 deaths from small-pox in 1896 in his own county, in the neighbouring city of Gloucester ; and, finally, the perilous experiment of leaving the decision as to whether vaccination should be done or not to the discretion or indiscretion of each head of a family. I am bound, however, to state that the perilous experiment is turning out much better than could have been expected Truly you will mourn with me over those 443 preventable-deaths in Gloucester, one of them of a vaccinated child and 297 of them of unvaccinated children under 10 years of age, when you reflect that during the same year and the next ,one there were, in well-vaccinated and revaccinated Germany, *only 15 deaths from small-pox throughout a* population of 53,000,000 Does anyone want more proofs? If so, they have them in the records of our own profession, which suffers from a general zymotic mortality far beyond, but from a small-pox mortality far below, the average , and this though we of necessity are much more than the general public exposed to the infection of small-pox We, ladies and gentlemen, know the truth and how to act up to it, and most earnestly do I wish success to Dr. F. T Bond and to the Jenner Society in their truly philanthropic enterprise of combating error and disseminating truth. I will say no more of Jenner and his work, though in this town, the former centre of his activity, I could not well say less , I must, however, add that the sad experience of Gloucester has not been fruitless and that Jenner's county is now perhaps the best protected against small-pox of any in England

Dr Ferguson next proceeded to consider

The Medical Standpoint of To day the Result of Scientific Research

He said: Pondering over medicine as it stands to day, the main fact that strikes me about it is how much more it owes to the biologists and to the men of pure science than to the so-called practical men The practical man is indispensable, but he is not like the great biologists, a high priest of the arcana of nature The cell theory, *for example, lies at the very foundation of modern* medicine, and this theory certainly originated entirely with the biologists The term "cell" was first used in reference to plants in the seventeenth century (1665) by Hooke who, with his contemporaries Grew and Malpighi, distinctly foreshadowed the cell theory of modern times , The cell nucleus was actually seen and drawn by F Bauer so long ago as 1802, though it was not before 1831 that it received that name from Robert Brown, the botanist. Little notice, however, was taken of the subject before the publication of Schleiden's paper on Phytogenesis in Müller's *Archiv* for 1838, in which he asserted that "every plant is an aggregate of individualised, independent, separate beings—namely, cells" Theodor Schwann, also in the next year, made a similar assertion regarding animals in his "Microscopical Researches," of which, and of Schleiden's paper also, the Sydenham Society published a translation in 1847 Schwann was first impelled to his conclusion by noticing the extraordinary resemblance between the microscopic structure of the chorda dorsalis of the tadpole and that of the onion and of certain pollen matrices Schwann, however, fell into error in asserting that cells arose spontaneously, and here he was set right by Barry in 1838 and later by Goodsir, who established the direct descent of every cell from a pre existing one This is Virchow's "continuity of life," his "*Omnis cellula e cellulâ*," the aphorism which he offers us in the place of Harvey's "*Omne vivum ex ovo*" That *punctum saliens*, the nucleolus, was first noticed by Schleiden, though it was Schwann who gave it that name Next came Hugo von Mohl in 1846 who recognised what we now call protoplasm in the cells of plants, the identity of which with a similar substance in the cells of animals was soon afterwards proved by Cohn and Remak. To Schwann a cell without a wall and a nucleus was no true cell, but Leydig in 1856 adduced pus and mucus corpuscles as instances of wall-less cells, and so step by step the ground was cleared for the now historical cellular pathology of Virchow, which influenced so profoundly the medical thought and practice of 43 years ago To Virchow, as to Schwann, a cell wall was a necessity, though this idea was soon afterwards dispelled by Lionel Beale and independently by Max Schultze in 1861 To Max Schultze we owe not only the extension of the term "protoplasm" (the bioplasm or living matter of Beale) to the contents of animal cells also, but the best description of an animal cell—namely, that it is a protoplasmic mass containing a nucleus This work on the cell theory gave the original inspiration to Pasteur, and Pasteur leads up to Lister, of whom I will forbear to speak, for he needs no speech, though he might well say of himself, "*Quæ regio in terris nostri non plena laboris?*" I may mention this significant fact, however, that visiting the Polyklinik in Vienna two years ago I noticed that the only name of a contemporary Briton inscribed on its façade was that of Lister. The cell theory, further, leads up to bacteriology, the most imposing and the most impressive department of medical biology Now bacteriology, which originated with the labours of Cohn and De Bary, rests on cultivation and staining; and if year by year *more and more of the* germs of disease are recognised it is because improved methods are constantly being perfected for colouring and making visible these formerly invisible entities The modern practice of staining, so essential to the physician and surgeon of the day, began with the botanists Göppert and Cohn who used carmine in 1849 and here again the pure scientists showed the way to the practical investigators of medicine, such as Gerlach of Erlangen, who first applied the method to anatomy In 1871 and later Weigert succeeded in demonstrating nuclei by ammoniated carmine and cocci by methyl violet In 1872 Eberth and Wagner began the use of that admirable stain, hæmatoxylin Looking through some old preparations of mine not long ago I found that most of those stained with aniline dyes were faded, but those stained with hæmatoxylin were still bright and good In 1879 Ehrlich enunciated his remarkable generalisation that the basic coal tar colours (like fuschin, methylene blue, and methyl green and violet) stain nuclei , whilst the acid ones (like orange green) stain plasm, and the neutral ones (like rosaniline picrate) stain special cell contents Weigert, later, found that acid fuchsin was specially useful in the study of the nervous system, and Strasburger, the botanist, used the basic methyl-green to demonstrate those mitotic figures which are of such importance in embryological work and have afforded a basis for the wide generalisations of the biologist Weismann Nor need I pursue the matter much further than to state that in 1882 Koch, who had previously devised the method of cultivation of bacteria, first stained with methylene blue and thus discovered the bacillus tuberculosis, the consequences and far-reaching results of which discovery are well known to all of you. That I have said so much on this point is to strengthen my contention that the true basis of modern medicine is essentially scientific As an admirable instance of the kind of debt that *modern medicine owes to bacteriology, of its power and* promise, as also of the extreme difficulty and complexity of the subject in its recent developments, I cannot do better than to advise the re perusal of Dr Horton Smith's Goulstonian Lectures on Typhoid Fever

In surgery the discovery of the Roentgen rays has been of priceless benefit, and the Cheltenham Hospital was, I believe, among the first of provincial hospitals to make use of these rays, but most certainly Roentgen was thinking of nothing less than *of surgery when in the modest Physical* Institute of Wurzburg he undertook his epoch making research on the cathodic rays of Sir William Crookes I have been to that modest but celebrated laboratory at Würzburg and heard there the true story of the discovery, which I must not here stop to relate though I may remark that I have never seen it correctly reported in English

I spoke of the antitoxins as among the most valued resources of remedial art, and it is to strictly scientific investigators, to such men as *Löffler and Roux Behring and* Kitasato, Haffkine and Yersin, that we owe these great discoveries Soon I believe, we shall possess antitoxins for most of the febrile and infective diseases as undoubtedly effective as is that one now so successfully employed against diphtheria. Personally I place much faith in the anti-typhoid inoculations of Professor Wright of Netley, and in the anti-tetanus serum and I feel sure that many more equally effective and similar means will soon be in our hands against other diseases *But it is not the practical physician* and surgeon who will discover them, but the intellectual devotees of pure science steadily pursuing through good and evil report, their self appointed task of universal beneficence.

The animal extracts stand on a different basis the basis of secretions destined not for excretion but for internal and bodily use, as first divined by Claude Bernard and so indispensable that without them disease or discomfort at once arises I forbear to do more than allude to the recognition of myxœdema by Sir William Gull in 1873 to its naming and the discovery of its connexion with an atrophic condition of the thyroid gland by Dr Miller Ord in 1877, and to the discovery by Mr Victor Horsley in 1890, of its antidote in thyroid transplantation, for which Dr G R Murray of

Newcastle soon afterwards substituted subcutaneous injection of thyroid extract, and Dr. Hector Mackenzie the much pleasanter method of thyroid feeding. I likewise merely mention ovarian extract which often mitigates markedly the miseries of the menopause and suprarenal extract, which, with its extraordinary power of contracting blood-vessels and of consequently raising the blood-pressure, must necessarily have a great future in therapeutics. The animal extracts (not wholly unknown to the ancients though first studied in modern times by Brown-Séquard) have doubtless a great future in practical medicine, and ere long many more will be in use, though doubtless some already proposed will fall short of their promise and pretension.

In thinking of the standpoint of to-day I next recall the splendid work—purely scientific again—of the French and Italian investigators of malaria, of Laveran in 1880, and more recently of Marchiafava and Celli, Bignami and Grassi, but more especially of Golgi, who first proved that the feverish attacks coincided with the sporulation of the malarial amœbæ. To which I am pleased to add that it is, as you know, the President of our Tropical Diseases Section, Major Ronald Ross, who, following the promptings and surmises of Dr. Patrick Manson, has discovered nearly the whole life-cycle of the protozoon, and not only that, but has identified the true delinquent and disseminator of malaria with the mosquito anopheles, a fact subsequently demonstrated by experiment on a human subject by the celebrated Italian biologist, Grassi; and still more recently by the experiment at Ostia in the Roman Campagna, where Dr. Low and Dr. Sambon and three others living by night for four months in their mosquito-proof hut retained their health; whilst Mr. T. P. Manson and Mr. George Warren (courageous sufferers for science), who were bitten in London by infected mosquitoes from the Sancto Spirito Hospital in Rome, developed soon afterwards every symptom of malarial fever. It seems that the hæmamœbidæ of malaria pass the whole of their life-cycle between animals and mosquitoes, and Dr. McCallum of Baltimore has further supplied the missing link of their sexual reproduction in the mosquito only. But the original hæmamœba can hardly have evolved itself in either. Whence, then, can it have originated? That is a question which I cannot answer, though I may refer to the statement made by Captain L. Rogers, I.M.S., officiating Professor of Pathology in the Medical College of Calcutta, that where pure and filtered water is drunk there but little intermittent fever will be met with. At all events, it is quite clear that vertebrate animals are the immediate hosts of the malarial germ, and that it has hitherto never yet been found in water or anywhere else, save in mosquitoes and in some vertebrated animals only. Elephantiasis, whose hæmatozoon, the filaria nocturna, was discovered in the blood by Surgeon-Major Timothy Lewis in 1872, is distributed by another mosquito, the culex pipiens or culex ciliaris, as first proved by Dr. Manson. And even this does not exhaust the delinquencies of these dangerous insects, as there can be little doubt that they also disseminate yellow fever; witness the experience of the American army surgeons in Cuba, where that scientific martyr, Dr. Jesse W. Lazear, though isolated from yellow fever cases, yet died from it seven days after submitting to the puncture of an infected mosquito, and Dr. James Carroll, under similar conditions, narrowly escaped with his life This particular mosquito has recently been recognised by the United States surgeons as the culex fasciatus, and it is probable that the transmission of yellow fever is due to it alone. The study of tropical diseases has, in fact, now become a refined department of biological investigation. Smith and Kilborne have shown the part played by ticks in disseminating the cattle fever of Texas, and ticks also are said to be responsible for the miana disease of North Persia and for a dysenteric fever of the Zambesi. Some forms of dysentery, as first suggested by Lösch in Russia in 1875, are probably originated by an amœba. In this town of Cheltenham old cases of malarial fever are often met with in returned officers and civilians, and I have yet to see the case that will resist six subcutaneous injections of three grains each of the acid hydrobromate of quinine.

What would have been the state of ophthalmology to-day without the invention in 1851 of the ophthalmoscope by the physicist Helmholtz? Then consider the benefits conferred by electricity. It may be that great results will follow some day from cataphoresis or the electrolytic introduction of drugs. There is no doubt in my mind as to the benefit in gynæcological work conferred by the treatment of Apostoli. Dr. Thomas Keith is not likely to have been mistaken in this matter, and what I have myself seen of permanent cures of really serious cases makes me feel sure that the Apostolian treatment for fibroids is not the delusion that some persons, who perhaps have not quite mastered it, proclaim it to be. It is, indeed, tedious, uncomfortable, and troublesome, and I for one shall be only too pleased if Sneguireff's simple treatment by superheated steam should prove itself an efficient substitute. Then there is the marvellously successful treatment of lupus by the chemical rays of the electric arc, devised by Finsen of Copenhagen, though it is a question again if these results are any better than those of Hannover, speedily obtained by a simple jet of heated air (atmocausis).

Where should we be without the scientific chemists?—to cite a few names only—Courtois, who gave us iodine in 1811 Balard, who gave us bromine in 1826; Serullas, who discovered iodoform in 1822; Soubeiran, who discovered chloroform in 1831; Liebig, who discovered chloral in 1832; and Neimann, who gave us cocaine in 1860? Not one of these was a practitioner of medicine or, unfortunately, a Briton.

More Universities and Research Institutions Needed.

I think that I have said enough to prove that the progress of pure science means medical progress also, and that it is to the men of pure science that we must still look to hold aloft for us the torch of progress. I can only hope that in the great advances still to be made Great Britain and Ireland may play their worthy part; but I confess that I have my misgivings unless some improvements are made in our educational arrangements. As the result of several recent August visits spent in many of the continental capitals I have been struck with the thoroughness and scientific spirit everywhere there manifested, being very different, I regret to add, from the anti-scientific spirit which characterises most of the wealthier and more cultivated classes in this country. This anti-scientific spirit is only eradicable by the better education of the young. To what other cause can we ascribe the fact that although the aniline dyes were discovered in 1858 by an Englishman, Dr. W. H. Perkin, yet almost the whole of their manufacture is now carried on in Germany. One company, the Badische Anilin und Soda Fabrik, employs 146 scientific chemists, 75 civil engineers, and 6300 workmen in one alone of its three factories. I know not if any words of mine will reach the eyes of those who govern in this country, but if they do I will implore them to give to our youth more facilities, similar to those enjoyed on the continent and in America. I know that much has been done and no fault is to be found with our primary education. The National Physical Laboratory and the Jenner Institute of Preventive Medicine have been established, the former in principle, the latter in reality, thanks to the splendid munificence of Lord Iveagh. New colleges, universities, and technical schools have been started and some 15 to 17 research scholars are appointed every year, one half of whom, I may remark, proceed at once to Germany to make their researches! What has been done, however, is as nothing to what ought to be done. The defences of the empire must not be overlooked, but of what avail will be, those defences if our trade is gradually lost for want of exacter knowledge? For trade and medical progress and those very defences themselves rest entirely upon progressive science. Depend upon it, there is as much scientific ability and aptitude for research in the country of Cavendish and Priestley, of Faraday and Kelvin, of Darwin and Huxley, of Jenner and Lister, of Rayleigh and Ramsay, as in any foreign nation, but here the chances and opportunities are much fewer, and many a great discoverer that might have been, one of whom it might have been written that—

> "He broke his birth's invidious bar,
> And grasped the skirts of happy chance"—

spends his untrained energies in futile efforts and vain regrets and wholly wastes his commanding intellect for the want of instruction and opportunities easily accessible.

But the cost! It would be as nothing in proportion to the gain, and a Faraday, a Koch, or a Pasteur would be a cheap purchase at a million. Whereas France, Germany, and the United States educate at their universities approximately one student in every 1500 of the population, we in the United Kingdom are content with less than 1 in 2000. Whereas Germany spends £753,000 a year on its 22 universities and France £740,000 a year on its 16, we in

Great Britain and Ireland are content with less that one-fifth of that amount—namely, £135,339 among seven of our 13. Although the Leland Stanford University of California has received no less than £9,000,000 sterling from private munificence and many others of the 480 American universities and colleges have likewise received huge sums—I may specify the Chicago University £2,000,000, the Johns Hopkins University £1,400 000 and the Cornell University over £1,000,000—no such general largesse is, I fear, to be expected from our British millionaires. The help must come from Government, supplemented by local contributions, or it may not come at all. Yet the matter is one of life or death for the country, for more and more every year the victory in every department and the predominance in arts and trades will pass to the possessors of the latest knowledge, the deepest science, and the most perfect and most economical processes. I cannot but believe that this great need will soon be remedied and that at the cost of a few battleships real universities of teaching and research, like the new University of Birmingham, will be established in every large town, and technical and research institutions—there are 25 of these in Germany and 43 in America—in most of the smaller ones. At present we are feeling keenly the competition of America a competition that is not likely to diminish, for it possesses over 100 schools of chemistry and has 10 000 students of engineering. This competition we can only hope to resist by imitating the foresight, generosity, and enthusiasm for science of the American Governments and of the American men of wealth. And here I would wish to quote the words of Dr T. K. Pearsons of Chicago, himself the donor of £800 000 to its University. "Monuments and monumental arches," he says, "once finished become dead memorials, their active function ceases. The school and college live, just as does the memorial in cold statuesque granite, but *their* functions never cease, education goes on from day to day, thinkers are moulded the nation is served, humanity is benefited in the college." Oh, that these words may find a practical echo in this country. Examinations are of secondary consequence. China is the most examined country in the world, and look at it. Original work done under the professor's eye and at his suggestion is far better than any examinations and the true ideal of a real university must always be in the words of Paulsen "*Die Erkenntniss der Dinge durch freie Forschung*" ("True knowledge from free research.") Let us hope that we shall not have long to wait for many such universities, where the best and most practical scientific education will be open to all at low cost, as in the University of Michigan, where the fees do not exceed £7 a year, or at no cost at all, as in the State of Massachusetts, and in many of the Western States of America. There is no time to lose. The Consultative Committee on Education is, however, a good beginning which I sincerely hope will soon be followed by the appointment of a Minister for Education a functionary to be found in nearly every civilised State except our own. It is not trade unions and skilled workmen that can insure the continued prosperity of a nation but the trained intelligences that direct its energy, and we may rest assured that whichever nation shall elevate highest the general standard of education will be the nation which will lead the world. Since the preceding section was written I have to record the magnificent—I hope it will prove infectious—generosity of Mr Andrew Carnegie, with his gift of £2,000,000 to the Scottish Universities one portion of it to be applied mainly to the teaching and endowment of research and the rest to replace the fees hitherto paid by their students. Happy Scotland that not only receives about one third of the whole Parliamentary grant for university education but has found besides such a princely and far-seeing benefactor as Mr Andrew Carnegie.

The Public Health Act of 1875

Any reference to the medical standpoint of to-day were quite imperfect without some mention of the important position now happily assumed by the sanitary medical service, and it is a matter for legitimate pride that in this particular Great Britain was beforehand and set, by the Public Health Act of 1875, an example that foreign countries, with the exception of the United States and of Belgium, seem in no great hurry to imitate. In every town and district there is now a skilled expert who is the guide, philosopher, and friend of every household where epidemic disease makes its appearance. It is to the labours of such as he and to the existence of isolation hospitals that the great diminution in the zymotic death rate is due. To his labours and to the increased cleanliness and better food of the population generally are due the gratifying diminution of the phthisical death rate within 60 years from 38 to 13 per 10,000—the presage, I cannot doubt, of the total abolition at no distant date of consumptive and tuberculous disease altogether. And this, although Naegeli has recently proved that, at any rate as far as Zürich is concerned, 96 per cent. of the deaths under 18 in that town are due to tubercle. To Dr Nathan Raw and to the guardians of Liverpool must be given the great credit of taking the first deliberate steps for the stamping-out of tuberculosis by establishing a rate supported sanatorium near Heswall for the isolation and treatment of the consumptive poor—a good example, likely to be largely imitated soon throughout the country. Here I would wish to solicit a generous and helpful interest in the sanatorium of 60 beds to be built at Limpley Stoke, near Bath, in which the consumptive poor of the counties of Gloucester, Somerset, and Wilts will be treated with every advantage of hill air, full dietary, and modern science. Pure air implies at least no fresh infection, and high feeding, as so convincingly shown by Sir Hugh Beevor at the last annual meeting, occasions an enhanced resistance against the tubercle bacilli.

The originator of the method of high feeding and fresh air was undoubtedly Dr George Boddington of Sutton Coldfield, by whom it was devised and carried out with great success so long ago as 1836. Most of the credit, however, of advocating persistently and quite independently the necessity and importance of fresh air must be given to the father of the distinguished recent President of the Royal College of Surgeons of England—namely, to Dr Henry MacCormac of Belfast, whom it was my privilege to know in my youth, and well do I remember his striking book, "Consumption and the Breath Re breathed." Like Semmelweis, the earliest of antiseptic obstetricians, and like Harvey, whose subversive discovery only brought about the loss of most of his practice, Dr MacCormac excited at first opposition and ridicule only. The more reason, therefore, that full credit should now be given to the impassioned and eloquent advocate of fresh air, who anticipated by more than half a century some of the best knowledge and practice of to-day. Here, then, is a method half English and half Irish in its conception, however much it may have been pushed and popularised during recent years in Germany. And there can be no doubt as to the cures. Soon after Koch's discovery of the bacillus tuberculosis I looked for it and found it at once in phthisical sputa and each finding was sentence of death, but now it is found as a simple matter of diagnosis to disappear completely and often finally at the completion of the cure by fresh air and high diet. Of the contagiousness of phthisis I can entertain no doubt whatever, and the greatest care should be taken to destroy sputa. Remembering the liability of birds to phthisis Dr Tucker Wise's cautions as to cage birds should not be forgotten. Indeed the connexion of the lower animals with our diseases must never be overlooked. The "harmless necessary cat" is quite often the conveyor of diphtheria, the dog always of hydatids and the rat often of plague. "No rats, no plague" it has been said and he who would exterminate his city's rats would do much to insure his city's immunity against the plague. In the case of Glasgow however it is right to add that the rats were guiltless.

Aspirations, Ethics, and Conclusion

And now for a few concluding words about the aims, the aspirations, and the ethics of the profession. After a long and expensive education after knowledge acquired laboriously and at great personal risk (the clergyman's death rate is 16 per 1000 the lawyer's 20 per 1000 and the medical man's, 25 per 1000) the medical man must not hold himself too cheaply. He is the heir of a long tradition, originating from the sages of India and from the temples of Greece. Our health and happiness are in his hands and the issues of life and death tremble often upon his judgment. So he must bear himself with confidence and proper pride, remembering his great traditions and the antiquity of his calling, which ranks next to that of priest. He is worthy of his hire and that hire should be such that in the day of his popularity he may make due provision for his age and retirement and for those whom he will leave behind him. He must work hard and read and think all the days of his practising for the best practice of to-day will not be that of even five years hence. His aspirations must be for the very best in each department of practice for the progressive advancement of his art, and for the increased dignity and consideration of his calling.

Above all, let him be chary of any commerce with the enemies of science. *Magna est scientia et prævalebit.* None the less serious is his responsibility who, knowing its benefits, yet retards its progress, or who ignorantly would deny to others what he is insufficiently instructed to understand for himself. Beware of panaceas. There are none in truth, though the worship of Panacea was not confined to Ancient Greece and is as reprehensible in the cold clear light of twentieth-century science as is the equivalent assumption by too many of specialist omniscience.

The wise practitioner will strengthen his position, as he will certainly increase his knowledge by somewhat frequent consultations, and he will do well if, like Hunter and Jenner, he cultivates some extraneous intellectual interest to relax occasionally the stress of his anxious labours. I venture to think that nothing will do him more good than the pursuit of one or other of the arts, or of some branches of biological or physical distraction, be it zoology or botany, electricity or telescopy, for

> "Neque semper arcum
> Tendit Apollo."

And the quotation is apposite, for was not Apollo the first physician and the father of Æsculapius, and does he not say of himself in *Ovid*—

> "Inventum medicina meum est, opiferque per orbem
> Dicor, et herbarum subjecta potentia nobis"?

The wise practitioner, moreover, will confine his studies within certain limits if he wishes to attain to a thorough knowledge of even some portions of his great subject. He cannot be a universal specialist, and I would commend to your consideration the admirable advice contained in one of Goethe's sonnets:

> "We [illegible] ammenraffen;
> In [illegible] ch erst der Meister."

For which I would propose the following English equivalent:

> "Who would be great must pull himself together;
> The Master shows himself in limitation ever."

The good and worthy practitioner will never be wanting in sympathy. Too often there is physical pain to be relieved, and, thank God, it can be relieved; though at other times the sufferings will be nervous rather than physical; and these are the occasions when sympathy and patience are most needed, though it is not always easy to show the first and to retain the last in the interest of some nervous sufferer on a cold wet night at 3 A.M.

In respect of medical ethics the case is very simple. Treat and think and speak of your brother practitioners as you would wish them to treat and think and speak of you. Medical ethics are, indeed, so completely summed up in this single sentence as to make it quite unnecessary for me to read to you the section that I had written on this subject. With high aims and aspirations, with true ethical, that is to say, brotherly, feeling, and with constant consideration for the public weal, we shall each and all be worthy of the well-known description in Chaucer, and be "veray parfit practisours," though I hope it will not be said of us, as it was of that particular one, that

> "His studie was but litel on the Bible."

No; we will read Ecclesiasticus, though not Ecclesiasticus only, in the hope that it may be said of each of us in the words of an old poet who was writing of a good and brave physician of his day:

> "He holds no parley with unmanly fears,
> Where duty calls he confidently steers,
> Faces a thousand dangers at her call,
> And trusting in his God surmounts them all."

After Providence, ladies and gentlemen, reason is and must necessarily be our daily guide, for which cause it is consoling to recall the words of one of the greatest of French writers:

> "La Raison triomphe de la mort, et travailler pour elle,
> C'est travailler pour l'éternité."

And if I have mentioned the word *la mort* it will but afford me the opportunity of concluding with my solemn conviction, as best expressed in the words of Longfellow:

> "There is no death! what seems so is transition;
> This life of mortal breath
> Is but a suburb of the life elysian,
> Whose portal we call death."

SECOND GENERAL MEETING.

The second general meeting was held in the Princess Hall of the Ladies' College on Wednesday, Dr. G. B. FERGUSON, the President, presiding.

The announcement was made that the next meeting of the Association would be held at Manchester next year, and Mr. Walter Whitehead, F.R.C.S. Edin., the President-elect, gave a most cordial invitation to the members of the Association on the part of the medical profession of Manchester and its neighbourhood.

The next item on the agenda was to receive the report of the representatives of branches, but the meeting insisted on passing at once to the consideration of

The Report of the Constitution Committee.

Mr. **EDMUND OWEN**, the chairman of the committee, in moving the reception of the report, said that the Constitution Committee was not a "packed" committee—the members represented England, Scotland, Ireland, and Britain beyond the seas. The attendance was excellent, for the members from all quarters of the empire attended a little more than seven out of the total number of nine attendances. When he (Mr. Owen) was appointed his friends said that he was running great risks because Mr. Horsley was on the committee. On that point he had to say that Mr. Horsley had served on many committees, and the British Medical Association was beginning to know what they owed to Mr. Horsley, but the profession at large did not know it. Mr. Horsley was a simple-minded man; he had no axe of his own to grind; he was not seeking personal advancement but was always ready to fight the battle of any part of the British Medical Association that was in distress. Mr. Horsley's conduct in the committee was quite admirable; he did not go to sleep and he would take it as an affront for a chairman to go to sleep, and he would advise any chairman on a committee with Mr. Horsley not to fall to sleep. After complimenting Mr. J. S. Whitaker of Yarmouth on the assistance he had rendered the committee Mr. Owen explained that the Association was a limited liability company.

Mr. **VICTOR HORSLEY** said he would like to commend to their notice the report of the Constitution Committee. At Ipswich they passed the resolution for the appointment of the committee to consider the reorganisation of the Association. He knew that while that committee was at work many members of the Association, like many members of the committee, felt that a very heavy and responsible work was being done within the Association. Further, they felt that it was the work of the profession and not merely that of this Association. Their members now had reached such a figure that they could refer to themselves as the "body" of the profession. He was sure that the Constitution Committee, in presenting this report, were anxious that they should realise how representative their discussions were. They wished to make this Association so representative in character that when on the rare occasions that the Association met its vote in general meeting assembled should go forth to the general public as being what the profession wanted. He had served on a committee of this Association on a burning question which he would not mention by name under these circumstances, and the most difficult position of the members of that committee was that they had no means of ascertaining what were the wishes of the members of the Association, let alone the ideas that prevailed in the profession as a whole. There was no means of getting at the wish of the profession. They were in this position—they were mighty in numbers but most weak in influence. Surely the recent proceedings in the House of Commons should be enough to remind them of their powerlessness in the way of coöperative influence. Under these circumstances the committee had worked and he had simply to commend to their favourable consideration the report of that committee. He had much pleasure in seconding the resolution:—

That the report of the Constitution Committee be received.

This motion was carried, as also was the next which was as follows:—

That this meeting, without prejudice to the further consideration of details, approves genera[illegible] proposed in the report and recomme[illegible] anising the [illegible] Acts, of [illegible] ns and [illegible] representative meeting and transferring [illegible] much as possible of the business hitherto brought before the general meeting.

This motion having been carried the recommendations of the committee were submitted *seriatim* and the first 15 were passed without any alteration except that of making "fourteen days" in Clause (*b*) of Recommendation 8 read "twenty-eight days."

Primary Unit.

1. That the primary unit of organisation of the British Medical Association be such that every member of a unit shall have a reasonable opportunity of attending every important meeting thereof, and that such unit be called a "division"

Divisions.

2. That in the United Kingdom the members resident within the area of each branch be grouped in divisions in such manner as may be decided upon by the branch with the sanction of the Council of the Association, regard being had (*a*) to the wishes of the general body of members in each district and the means of communication by rail or otherwise, (*b*) to the desirability, for more effectively carrying out the work of the Association, of the boundaries of divisions being made to coincide as nearly as possible with those of Parliamentary constituencies or groups of constituencies

Divisions—Indian and Colonial

3 That in the colonies and India divisions be formed by each branch in accordance with the general principle of recommendation (1) where the local special conditions permit, but that where existing branches remain undivided with the approval of the Association each such branch be regarded also as a division for the purposes of these recommendations

Branches

4 That the divisions be combined to form groups called branches, the desires of divisions being complied with in the grouping so far as is compatible with efficiency of organisation and the general interests of the Association. That the boundaries of branches be made eventually to coincide as nearly as possible with those of counties or groups of counties, but that for the present time the existing branches be taken as the basis of rearrangement and act as such groups of divisions for the purposes of these recommendations.

Membership of Local Organisation

5 That every member of the Association be *ipso facto* an ordinary member (hereinafter called a member) of the division within the area of which he resides and of no other

Election of Members through Branches

6 That the election of new members resident within the area of a branch be through that branch only, and that the rule relating to the election of such members be to the following effect:—

Qualification for Membership

Any registered medical practitioner may be elected a member of the bra[illegible] has [illegible] agr[illegible] of [illegible] pay[illegible] po[illegible] not [illegible] election is to be considered

Complimentary Members.

7. That any branch or division have power to elect as a complimentary member any member of the Association not eligible by residence for ordinary membership of such branch or division, and that any colonial or Indian branch or division have power to elect as a complimentary member any qualified medical practitioner resident within the area thereof, but not eligible by birth and qualification for membership of the Association; that complimentary members be not permitted to vote as members of the branch or division, but otherwise have such privileges of membership as may be conferred on them

8 That the rule relating to expulsion be to the following effect:—

Expulsion ipso facto.

(i) Any member of the Association who shall have been convicted in a court of justice of any felony or misdemeanour, or whose name shall have been erased from the Medical Register under Section 29 of the Medical Act, 1858, shall, *ipso facto* cease to be a member of the Association

Expulsion by the Council.

(ii) (*a*) The Council shall have power in all cases, on the representation of any branch and after due inquiry, of which the member involved shall have received due notice, to expel any member whose conduct is held to be detrimental to the honour and interests of the medical profession and calculated

Majority required.

to bring the profession into disrepute, but a majority of two thirds of the members of the Council present and voting shall be required for this purpose

Expulsion by Indian and Colonial Branches

(*b*) In the case of colonial and Indian members each local branch shall have power to expel from membership of the Association any member of such branch whose conduct, after due inquiry at a special meeting convened at not less than one month's notice, shall be declared by a majority of two-thirds of members present and voting at such meeting to be detrimental to the honour and interests of the medical profession and calculated to bring the profession into disrepute. The name of such member shall be notified to the general secretary and shall be forthwith erased from the Register of Members of the Association kept at the central offices of the Association, unless such member shall appeal within 28 days to the Council to hold a further inquiry, and pending such inquiry by and decision of the Council his membership shall be suspended

Non-acceptance of Resignation.

(iii) No member whose conduct is under investigation or is the subject of any inquiry by a branch or by the Council shall be allowed to resign his membership of the Association until the decision of the branch or Council be made known.

Composition of Branch Council.

9 That the C[illegible] its membership

Division Administration

10 That any [illegible] to [illegible] tive [illegible] pre[illegible] vers [illegible]

Reports of Status of Branches and Divisions

11 That each division furnish annually to the branch council, and each branch to the central council, a report of its proceedings during the year, its numbers, and its financial position

Branch By-laws and Rules.

12 That all branch and division by laws and rules be submitted for approval to the Council of the Association and do not come into operation until approved by the said Council

Local Autonomy

13 That subject to the above provisions and to the fundamental laws of the Association, as declared in its articles and by-laws, each branch and each division be free to govern itself as it shall think fit

Central Council Composition,

14 (i) That the Council of the Association consist of the President, President-elect, past president for the year following his year of office as president, and treasurer, all *ex-officio*, of representatives elected by the branches as hereinafter provided, of one representative each elected by the members of the Association attached to the Royal

Naval and Military Representatives

Navy Medical Service, the Royal Army Medical Corps, and the Indian Medical Service respectively, and of members, to be not more than

Coöpted Members

one tenth of the elected members, annually coöpted by the Council, the same member not being coöpted for more than five years successively

(ii) That in general each branch or group or branches having an aggregate membership of not less than 200 return one representative, and each branch or group of branches having an aggregate membership of not less than 400 return two representatives and an additional representative for each complete 600 members in excess of 400, that branches in the United Kingdom having less than 200 members be grouped with neighbouring branches for the purpose of representation on the Council, but that the Council have power to grant separate representation to such branches where special conditions appear to the Council to justify this measure.

Election

(iii) That the representative members of Council be elected by [illegible] the said voting papers con[illegible] have been nominated each [illegible] ry on or before an appointed [illegible] tice has been given in the Journal

Eligibility for Re-election

(iv) That the term of eligibility for continuous office as a representative member of Council be limited to eight years after which a term of one year's ineligibility as a representative member shall ensue

Term of Office United Kingdom Branch Representatives

(v) That the representatives of branches in the United Kingdom on the Central Council be elected for one year and be eligible for re-election subject to the provisions of sub clause (iv)

Colonial and Indian Branch and Service Representatives

(vi) That the representatives of colonial and Indian branches and of the Royal Navy Medical Service the Royal Army Medical Corps, and the Indian Medical Service on the Central Council be elected for such period not exceeding three years as each such branch or body may determine, and be eligible for re-election subject to the provisions of sub-clause (iv)

Powers of Council

15 That except as herein otherwise provided the management of the affairs of the Association be vested in the Council subject to the provisions of the articles and by laws of the Association

---

THE SECTIONS.

MEDICINE

WEDNESDAY, JULY 31ST.

The Presidential Address

Dr. E T WILSON, physician to the Cheltenham General Hospital and to Cheltenham College, opened the work of the Section of Medicine with the following introductory remarks —

The Value of Research in Medicine and Therapeutics

In offering a few informal remarks by way of preface to the real work of the section my first impulse is to express my deep sense of the honour which has been conferred upon me by my professional brethren in electing me to this chair, with which so many names honoured in medicine have been associated; my second is to add a few words to those of the President, bidding a hearty welcome to all who from far or near have come to visit our good town of Cheltenham, wishing them that healthy combination of work and enjoyment which it is the object of these annual meetings to afford. Here we mark time, as it were, and take stock of the work done in our several departments. The experimentalist and the specialist meet with the general practitioner on a common platform with the best results. The times are favourable to such conferences. Increased facilities for communication and for the interchange of thought have in a sense annihilated space. The rapid evolution and general trend of modern medicine are shown by the way in which this section has of late years outgrown its ancient landmarks, throwing out colonies, as it were, in the Sections of Pathology and Bacteriology, Tropical Diseases, Diseases of Children, and others more specialised, which in some instances threaten to rival the parent in interest. The subjects which are to engage our attention in this section during the next few days deal with questions on which more information is urgently needed. The discussion on joint disease treats of disorders which are probably among the oldest known to humanity and opens up the whole question of infection by micro-organisms with which some of the papers in this section also deal. The second subject set down for discussion—Peripheral Neuritis in Beer-drinkers—is essentially modern, and although it is under investigation by a Royal Commission we shall have the advantage of hearing the views of gentlemen who are thoroughly conversant with the facts. Other papers there are dealing with therapeutics and among these one on the Cheltenham waters which flow unchanged, though mercilessly stripped of all the accessories appertaining to a spa. They would no doubt prove efficacious as of yore on the old conditions:

> "Curæ vacuus hunc adeas locum
> Ut morborum vacuus abire queas,
> Non enim hic curatur qui curat."

A paper on Malaria was hoped for; but the prior claims of the Tropical Section could not be questioned, for, although the tests which finally led to its conviction were applied on the Campagna of Rome, the guilty anopheles was arrested in India, and its prosecution followed up in the equatorial regions of Western Africa. This remarkable investigation is one of the latest contributions which microbiology has given to medicine and presents a signal example of the rapidity and thoroughness of modern methods. Activity prevails in every department of medicine and surgery, but in none have so many valuable results been obtained, in none have so many hopes been excited as in the scientific study of the infective diseases, of the exotic fauna and flora of the human body. The bacteriological diagnosis of certain diseases has become a matter of routine, and there can be little doubt that in the near future a need will arise for laboratories and specialists in every large centre of population, to whom questions insoluble or doubtful in their clinical aspects may be referred, on whom will rest also the responsibility for the supply of such vaccines and serums as may be required in their several districts. An improved diagnosis, however, is but a small portion of the gain which has been derived from a scientific investigation of the causes of disease. Over a large part of the field of therapeutics a new direction has been given to treatment. We are learning to look beyond the collection of symptoms which were once held to constitute the disease, with the result that, although symptoms will continue to claim our attention, and certainly that of our patients, the true objective of treatment will be the micro-organism itself. We are learning more and more at the hands of a new pathology to regard the human body as a battle-ground on which important issues have to be fought out between invading organisms and poisons coming from without, on the one hand, and on the other those forces inherent in the system, of which so little is known as yet, but which may be summed up in the term "resistance," or in one older and better known, the "*vis medicatrix naturæ.*" Every disease which can be won over for the infective class becomes at once, if only in theory, preventable, and our treatment acquires a tangible and definite aim. In the first line of defence comes the destruction of the parasite before it obtains a lodgment in this body, and this will be divided between the health officer and the medical attendant, for it comprises the whole array of hygienic measures, including the isolation of the infected sick. Our means of attacking the parasite within the body are at present limited in extent, but some progress has been made—as, for instance, in the treatment of lupus by sun exposures, of rodent ulcer by the x rays, and of tuberculosis of the lung by life in the open air. An additional defence is found in the vaccines by which immunity, artificial or natural, is secured, such as the Cuban enjoys against yellow fever or the vaccinated with cow-pox against variola. In serum-therapy we again appeal to powers which cannot at present be explained, whereby for each several toxin produced by an organism in the blood a special antitoxin is forthcoming, and it is the possibility of supplementing this supply by artificial means which has deprived diseases, such as diphtheria and tetanus, of the terror with which they were wont to be regarded. Lastly, behind all these, we have in reserve the enormous powers residing in the blood-cells of offering a successful resistance to the invading organisms—a resistance the vigour of which is easily impaired by unfavourable circumstances, and which it will become more and more the aim of medicine to foster and improve. The number of the infective diseases is by no means complete and it becomes almost possible to breathe a word of hope where despair has hitherto prevailed, that medicine may yet find work to do in the treatment, preventive it may be, of the neoplasms which occur with ever-increasing frequency. The cancer which the surgeon now removes with such consummate skill is not the disease; it had its beginnings in an insignificant outgrowth, during which the rapidly proliferating cells, estranged from their accustomed environment, would probably be vulnerable did we know how and where to attack them; and further back still lies the exciting cause, on the exact nature of which medical opinion is divided; there seems, however, good ground for suspecting that here, too, we are confronted with a micro-organism and an infective disease the remedies for which, though they be long in coming, cannot be regarded as beyond the reach of human attainment, for—

> "Let that man with better sence advize,
> That of the world least part to us is red;
> And daily how through hardy enterprize
> Many great regions are discoverèd.
>
> * * * * *
>
> Yet all these were when no man did them know,
> Yet have from wisest ages hidden beene,
> And [illegible] nowne shall show;
> Why, [illegible] so much misweene
> That nothing is but that which he hath seene?"

Dr. Wilson concluded an eloquent address by pointing out that in modern medicine the use of drugs—"the offspring of a wise empiricism"—had been unduly discredited, while the art of prescribing was falling into decay. Medical men, he considered, should take combined action to settle certain therapeutic questions.

Chronic Diseases of Joints usually Comprised in the Term Chronic Rheumatism, Osteo-arthritis, and Rheumatic Gout.

Dr. A. E. GARROD (London) then opened a discussion on this subject and said that the joints were so readily accessible to examination that their diseases attracted attention very early, and there was an immense amount of literature on the subject. It was very difficult to avoid preconceptions when approaching this subject, but it was absolutely necessary to do so. Acute rheumatism had been in turn regarded as a purely local affection of the joints, as a humoral disease, and finally as a specific infective fever, and similar changes of view had taken place with regard to the diseases now under discussion. There were many diseases of the joints which did not come under this heading. The arthropathies of bacterial infection, pyæmia especially, that form caused by gonococci, and others, as well as those accompanying certain diseases of the spinal cord, were instances in point. The nomenclature of these diseases was not satisfactory. The name of "rheumatoid arthritis" suggested a causal connexion with rheumatism; the name of "arthritis deformans" was less open to objection. In the same way the treatment of these affections was dominated by theories of gout and the name "rheumatic gout" had contributed to this. Certain changes were found in necropsies in these affections and the question that had to be decided was, are all these changes the result of one and the same morbid process? He distinguished two distinct forms—the first occurring more especially in women at the earlier periods of life, affecting first the smaller joints, and forming fusiform swellings which had a crackling sensation on palpation. Muscular atrophy was an early symptom; it seemed particularly apt to follow *debilitating causes, such as influenza. Its progress might* be either rapid or slow, the fever might be considerable or slight, and pigmentation of the skin was usually present, visceral lesions were the exception but albuminuria might occur Post-mortem examination showed that the synovial membrane was more involved than the cartilages The morbid anatomy of this form was not well known and more work was very urgently needed in this direction He compared this form, to which he referred afterwards as the fusiform variety to that in children described by Dr Still He also reserved the term rheumatoid arthritis' for this variety The second variety, also occurring mostly in females came on at a more advanced period of life, the terminal joints *and the carpo metacarpal joints of the thumbs being those* usually first affected. It was neither so painful nor so rapid in its course as the former variety Eventually many joints became involved and in place of the crackling they got grating in the joints and eburnation of the ends of the bone after absorption of the cartilage He thought that these two forms were not identical, they were different from the commencement and he preferred to reserve the term "osteo arthritis for the second variety He thought that the joint affection confined to single joints was a distinct disease Many people considered that these diseases had an intimate connexion either with acute rheumatism or with gout and he thought that the nodular disease of old persons was *rheumatic The fusiform variety was not due to the* results of acute rheumatism They might get severe or slight peri arthritis but as a rule there was no acute rheumatism in rheumatoid arthritis and the heart was seldom affected Though rheumatoid arthritis has occasionally followed acute rheumatism he could not see that there were any sound clinical grounds for thinking that acute rheumatism caused rheumatoid arthritis The rheumatic nodules in rheumatoid arthritis were not like those of acute rheumatism The distinction between the two diseases could not be settled by clinical methods Bannatyne and others seemed to show that if there were bacteria in the diseased joints those in cases of acute rheumatism were not the same as those of rheumatoid arthritis They should never forget that osteo arthritis was not connected with gout or rheumatoid arthritis with acute rheumatism If he was right in distinguishing between the two varieties it was clear that they could not have a common cause He recommended an expectant attitude on the question waiting for demonstration of the specific bacteria of the different forms of the disease With regard to treatment, all forms were very refractory He considered that we should try to exclude any debilitating conditions such as menorrhagia or dyspepsia and any unhealthy condition of the teeth or gums. These forms of disease should be treated with a low diet and stimulants were generally required In rheumatoid arthritis the patient's strength should be kept up and tonics given but in *such a form as not to upset the digestion. Cod liver oil* and arsenic were useful but all methods of treatment should be continued for a considerable time even though they were not immediately successful Osteo arthritis was less amenable to treatment though its progress was slower, the indications in this latter disease were to delay its progress as much as possible though he confessed that he had never seen any particular benefit arise from any form of treatment. He submitted the three following points for consideration 1 Are there two distinct forms of the disease? 2 Are either of them connected with rheumatism or gout? 3. What are the best methods of treatment?

Professor OSLER (Baltimore) emphasised the necessity for approaching the study of these diseases without bias and from a mutual standpoint If there were not two diseases there [illegible]

[illegible] mentioned other varieties which had been differentiated by foreign observers but he objected to these varieties being called different diseases

Mr W ARMSTRONG (Buxton) described some cases which he considered to bear out some of Dr Garrod's remarks

Dr A. P LUFF (London) thought that rheumatoid arthritis [illegible] a but that it was [illegible] toid arthritis was [illegible] Salicylates were *valueless in the former disease. He considered it was possible* to treat rheumatoid arthritis with success but we must always remember that we were dealing with a microbic affection of joints We must try to differentiate between all the different forms of arthritis As against the neurotic theory of the causation of rheumatoid arthritis he submitted that it was not symmetrical in early stages, he considered the muscular wasting to be simply due to disuse. There was no reaction of degeneration in the atrophied muscle and no nerve lesion had ever been demonstrated It was possible that a nervous affection might predispose to bacterial invasion by lowering the nutrition of the joints and he mentioned that he had under his care at present *six cases in which rheumatoid arthritis had followed the* removal of both ovaries He regarded the mono articular cases as a different disease and probably not microbic in causation With regard to treatment he thought that he had secured the best results from the application of radiant heat He advised a good and generous diet, a red wine and for drugs iodide of potassium and some guaiacol preparation—say, the carbonate—commencing with three doses daily of five grains each and working up gradually to about 45 grains per diem

Dr W P HERRINGHAM (London) said that there were two questions before the meeting The first was the diagnosis of osteo-arthritis from acute rheumatism and secondly, the *pathology of osteo arthritis An acute attack of osteo-*arthritis was very like acute rheumatism In both there were rash pain, and fever and both were relieved by salicylates Time alone would reveal the nature of the case He could not quite agree with Dr Garrod that there were two distinct varieties of the disease, he thought that the points of resemblance were more numerous than the differences He granted that in elderly people the disease attacked chiefly the bones and in younger ones the synovial membrane and in Dr Still's cases of children the large glands were involved, but he was inclined to think that the differences were not in the diseases but in the patients In old age diseases came to be more chronic, in children we [illegible] surfaces while in older [illegible] He thought that there [illegible] nt for deciding whether [illegible] t the true pathology of osteo-arthritis was

Dr C O HAWTHORNE thought that there was chronic rheumatism of the joints and that it was incorrect to say that these cases were never rheumatic

Dr F J CAVE (Bath) thought that many clinical kinds of arthritis might be produced by the same poison and conversely [illegible] poisons He had seen a [illegible] uced by infection from a [illegible] He considered that if we looked with sufficient diligence for an antecedent cause for rheumatoid arthritis we should in most cases be able to discover one. With regard to treatment he thought that serum therapy would prove the hope of the future

Dr SAMUEL WEST (London) considered the discussion of the subject to be difficult since observers were not agreed on a basis of classification Few varieties of joint lesions could be expected to be found post mortem and various causes must produce identical ones He thought that it was most important to recognise as early as possible the existence of any such cause as that mentioned by Dr Cave whose remarks he considered to be most valuable He also considered that the cause of infection in most cases could be found and therefore they ought to search for them diligently He quoted a case of his *own in which the only local cause* that could be discovered was a very slight cystitis, but after curing the condition *of the bladder the arthritis disappeared* He mentioned the connexion of joint disease with empyema, and concluded by saying that he thought that in many cases various bacterial forms might produce the disease

Professor R SAUNDBY (Birmingham) endorsed Dr West's remarks, he was inclined to take gonococcal rheumatism as the type of these cases and other infections acted in a similar way

Dr W CALWELL (Belfast) Dr ELIZA DUNBAR (Bristol) Dr SARAT K. MULLICK (London) and Dr PRESTON KING (Bath) took part in the discussion

Dr GARROD in reply thought that the discussion would do good he thought that during its course we had got a little out of a fog and that several peaks had emerged Comparing this discussion with one six or seven years ago he noticed an advance in general professional opinion towards a more scientific view of these cases.

The PRESIDENT closed the discussion in a few words.

Escape of Cerebro-Spinal Fluid from the Nose.

Dr. WATSON WILLIAMS (Bristol), and Dr. W. S. V. STOCK (Bristol) showed a patient who had an Escape of Cerebro-Spinal Fluid from the right nostril; there were no bad symptoms, but the continual flow was a nuisance to the patient. It commenced quite suddenly about four months ago and had continued ever since. Clinical tests showed it to be undoubtedly of the nature mentioned and not to be the fluid of a nasal hydrorrhœa.

Dr. STCLAIR THOMPSON (London) thought that the disease was very rare, but accurate diagnosis was necessary, or treatment might be employed which might be injurious to the patient.

Professor OSLER suggested lumbar puncture as a possible means of alleviation.

Dr. A. P. LUFF read a short paper

On the Composition and Therapeutic Uses of the Cheltenham Waters,

and said that his object in doing so was to induce practitioners to make more use of home spas. He wished that the corporation of Cheltenham could see its way to restore the spa as it formerly existed. Many cases which were sent to Carlsbad, Kissingen, Wiesbaden, Marienburg, &c., could be better treated at Cheltenham. There were two principal varieties of the waters—the first contained much sodium chloride and sodium sulphate, was a cold water, and resembled that of Marienbad; the other was a water containing a considerable amount of magnesium sulphate and sodium sulphate. The waters were useful in chronic constipation, obesity, and dyspepsia; and while they were not suited for articular gout they were very useful in irregular forms of that disease, such as intestinal catarrh, glycosuria, and also rheumatoid arthritis. The summer season was the best, though many thought that the town at that time was relaxing in its climate—an opinion which he knew, however, was not shared by the distinguished president of the section. But if Cheltenham were ever to attain the position as a spa and health resort to which the therapeutic value of its waters undoubtedly entitled it the spa should be provided with all those modern appliances and aids, such as baths of all kinds, massage, radiant heat, &c., which had done so much to restore the watering places both here and abroad to professional and public favour. The waters of Cheltenham were as good as ever, and if the authorities would bestir themselves their fame would be again re-established.

SURGERY.

WEDNESDAY, JULY 31ST.

Mr. REGINALD HARRISON (London), surgeon to St. Peter's Hospital and President of the Section, in place of a presidential address, opened the first debate of the meeting upon

Renal Tension and its Treatment by Surgical Means.

I drew attention in 1896, he said. to some cases where patients suffering from albuminuria and other renal symptoms which might have been produced by a stone or other removeable cause had completely recovered after an exploratory operation on the kidney by puncture or incision, though no calculus or recognisable cause was discovered. It seemed reasonable to infer from these results, as well as from the examination of the parts operated upon, that this satisfactory termination might be ascribed to the relief of tension and congestion, thus allowing the escape of that which caused these conditions and permitting the return of a natural circulation in the organ. Further, I urged that the recognition of tension as a factor in kidney disease had not hitherto received adequate attention and that its consideration might lead to some revision in our views relative to renal pathology and treatment. I propose to deal with this subject now briefly under three headings:—1. What grounds are there for believing that the immediate effects of tension may be, amongst other causes, the starting-point for some of those pathological changes in the kidney which are included under the term of Bright's disease or nephritis? 2. In what class of cases are there reasons for thinking that direct surgical intervention for the relief of tension and its effects is applicable, and how are we to arrive at this conclusion. 3. In what manner should the latter be practised?

In reference to the first point it must be borne in mind that the more recent information we possess about certain pathological states of the kidney has been mainly derived from the actual inspection of the organ during life and from the impressions conveyed by touching or handling it. The effects of tension as a factor in renal disease could not be fully appreciated until a living kidney could be explored *in situ*. The question has been raised, How is it that the tension of acute nephritis never or rarely proceeds to suppuration or gangrene, as happens elsewhere in the body? The answer is obvious. These extremes are anticipated by death There is another phase connected with pathological lesions of the kidney which should not be lost sight of. In my Lettsomian Lectures delivered before the Medical Society of London in 1888 I showed that it was not uncommon to find either as a consequence of direct injury or disease that the lining membrane of the urethra had, at one or more points, lost its power of transmitting urine without some degree of slow leakage or exudation of certain of its constituents in the direction of the peri-urethral tissues occurring. I attributed this to the destruction of the epithelial coat, which was found to be completely absent at these points. This led to lymph barriers being thrown out in the peri-urethral tissue which by their subsequent organisation and contraction formed strictures and indurations, and sometimes by their extent involved the perineum. The same, I believe, may happen in the inflamed kidney as a consequence of tension, and by the slow exudation of urine tend in aiding its disorganisation. Apart from evidence to be obtained from ocular and digital exploration of the kidney, which will be referred to later, there are some important analogies bearing upon internal tensions which must not be passed by unnoticed. Probably the most striking one is the relation of intra-ocular tension to certain diseases of the eye. The recognition of the true pathology of glaucoma and the adoption of mechanical treatment by iridectomy, or an allied operation for the removal of tension and the prevention of the [illegible] changes thus initiated, at once resulted in the [illegible] eyes which previously to this discovery would undoubtedly have been lost. By this means Von Graefe converted an incurable disease into a curable one and at the same time demonstrated the true nature of the disorder. Hence it has been suggested to me that the term "renal glaucoma" is not an inappropriate one. Again, in the testicle, when it becomes inflamed, we have not unfrequently transient as well as permanent evidence of the damage that inflammation and tension are capable of effecting in an organ which, relatively to its secreting and investing structures, is not unlike the kidney. The late Mr. Henry Smith was the first to draw attention to the advantages that followed puncture or limited incision through the capsule in acute forms of orchitis. It was correctly alleged that not only was the pain of tension in a highly sensitive organ relieved, but structural damage averted. In fact, sterility, so far as this organ was concerned, was by this simple means rendered unlikely to occur. It is, however, to the ocular and digital examination of the kidney during life that I would attach most importance relative to the subject that is now before us. This is a proceeding which may be regarded as an outcome of the general use of anæsthetics and antiseptics for almost all surgical proceedings. Before these were introduced the living human kidney was only seen on rare occasions in connexion with abdominal wounds accidentally inflicted and when the organ involved was in a healthy state. Now the operating surgeon may be said to be familiar with its appearance and consistence in all states of disease and injury. From my earliest explorations of the kidney I soon learnt to recognise that both in regard to its colour and consistence, apart from its size, there were very important variations to be observed which I had never seen in the organ after death. Later I observed that in some cases of albuminuria the albumin permanently disappeared from the urine after the kidney had been opened and permitted to drain, and thus the excretion became normal.

[Here Mr. Harrison narrated six cases in illustration of his points. The first was a case of scarlatinal nephritis, the second one of nephritis from exposure to cold and damp, the third one of subacute nephritis probably following upon influenza, and the fourth one of nephritis further complicated with an injury; all four cases were characterised by the presence of albumin in the urine, which he was inclined to attribute to inflammation or its immediate effects. The fifth and sixth cases represented other phases of renal tension. In reference to the second point, how they were to arrive at a conclusion as to the class of cases to which direct surgical intervention for the relief of tension may be applicable he said]

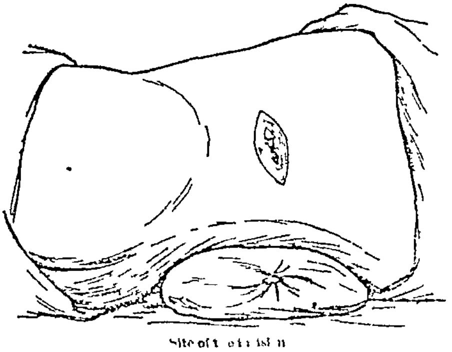
I can best put the case before you by taking types representing three states of acute nephritis which not uncommonly come under notice in connexion with scarlet fever The first is the common type where there are varying degrees of fever rash and desquamation with nephritis indicated by blood in the urine albumin casts and epithelium Cases included in this large class certainly do not require surgical attention for recovery is steadily progressive, and after a few weeks interval of illness and convalescence the congested organs return to their normal condition The second group of cases though apparently belonging at the commencement of the attack to the preceding class, does not end in the same way The previously healthy adult or child passes through the early stage of the disorder much as in the former instance but convalescence is delayed and the signs of the nephritis as evidenced by albuminuria and casts in the urine do not disappear The disease does not progress towards recovery, but is stationary and trends in the opposite direction These are the instances which furnish a considerable proportion of the cases of chronic nephritis or Bright s disease and a more or less invalid life is the prospect It is to this class and the following that the relief of t l to be applicabl hat has been desc- phritis Here the in the pathologi f urine occurs, and death rapidly follows from uræmia, with coma and convulsions After death under these circumstances it is usual to find the kidney intensely congested and the capsule tense and shiny and over filled with blood

[Mr Harrison then discussed the influence of the general tension thrown on the heart or circulatory apparatus in connexion with renal inflammation and concluded by considering the method of giving relief to renal tension under the conditions referred to He said]

The patient being anæsthetised and placed in the position for a lumbar nephrotomy the kidney is exposed by a transverse incision through the loin about parallel with and a little lower than the last rib (Fig 1) The length of the incision varies relatively to the consistence of the patient and the individual connexions of the kidney to be searched In spare subjects an incision of three inches probably suffices The various musculo fascial layers are divided until the suprarenal fat is seen. The connective tissue covering this should be opened up with probe and forceps, when the kidney may be recognised help being rendered by an assistant pushing up the organ in the direction of the operator There is seldom much bleeding or even necessity for tying a vessel If the organ has to be further explored as, for instance for a possible stone the kidney may be withdrawn through the wound for more thorough examination with the finger This however, is not necessary where tension alone exists Sufficient prominence for a limited incision through the capsule so as to relieve tension and secure drainage or even to puncture the organ, as for renal puncture can be given by an assistant in the way already mentioned In incising the capsule of the kidney for relieving tension I prefer doing so along the convex border Occasionally the incision may be indicated to one side or other of the free border as congestions and extravasations of blood are not necessarily evenly disposed throughout. Punctures may be made almost anywhere where the engorgement seems greatest but it is as well to avoid the pelvis of the organ either in the case of these or of incision I have frequently seen on puncturing the capsule for the purpose of exploring blood spurt out in jets as if projected under considerable contractile pressure and eager to escape The desired object being effected whether it is limited to the partial division of the tense capsule or the more thorough exploration of the organ as for stone a drainage tube is carefully inserted so as to remain in contact with the kidney and the wound is closed round the rubber outlet with silk sutures (Fig 2) The incision is dressed with gauze antiseptically As drainage is an essential part of the process and may be continued for some days or even weeks before the tube is removed, an ample supply of absorbent dressings should be used and renewed as often as necessary The drainage tube usually remains *in situ* from a week to 10 days but this entirely depends upon the nature and degree of the sanguineo-urinary discharge which is sometimes profuse and continuous On the removal of the drainage tube the wound usually heals rapidly I have never seen a permanent urinary fistula follow this proceeding The question in a case of nephritis sometimes arises as to which organ should be selected for exploration Unless there is something to indicate it such as the presence of pain my experience would lead me to believe that this is not a matter of much importance Both organs are usually involved in the inflammatory condition though perhaps it may turn out not to the same degree In double nephritis the relief of tension in one organ aids the other and thus as I have noticed on several occasions the normal amount and constitution of the urine becomes re established Similarly aid to an injured kidney by the removal of direct pressure caused by the accidental extravasation of blood either within or around it has been shown to assist the opposite one and to restore the balance of the urinary excretion when this has been diminished or entirely suppressed

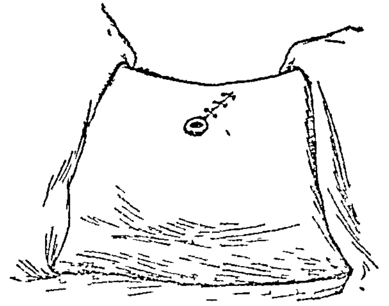
In this statement I have endeavoured to give prominence to those points which seem most deserving of consideration, relying more upon direct testimony than upon inferences drawn from lines of practice which can hardly be said to cover all varieties of this inflamed condition Nor have I made any attempt to elaborate my argument at this stage from such sidelights as chemistry physics or physiology might furnish but have confined myself chiefly to that which is clinical Propositions involving changes in well worn pathologies and practice cannot be approached with deliberation and no one is more conscious of this than myself "How far to use the words of a recent writer the operation of incision of the kidney can prevent or relieve the effects of congestion time alone can show but the subject deserves the careful attention of all surgeons "[1] I think

FIG 1.



Site of the incision

FIG 2.



Shows the wound closed

---

[1] Puncture of the Kidney for Nephritis The Lancet June 15th 1901 p 1698

enough has been said to show this. I thank you for your presence, and commend this subject to your candid consideration.

Mr. W. D. Spanton (Hanley) heartily endorsed the observations of the President. He had found free cutting of the loins alone of considerable use in such cases, and had operated on the organ itself in two cases of nephritis, one from exposure to cold and the other from injury, with good results. He considered the risks of this measure practically *nil.*

Dr. J. Ward Cousins (Portsmouth), said that he had obtained good results in the reduction of renal tension by free purging with the dry-air bath. In selected cases he thought the operative treatment good. What he would require was a history previously good with a freedom from earlier renal damage; if this was known to have occurred he thought surgical interference valueless. He believed such measures were admirably adapted for the treatment of the so-called "uræmic convulsions" of alcoholic excesses, provided there was a good previous history. He feared that the treatment was likely to be of no use where there was a sudden suppression of urine in cases of chronic renal disease with heart affection.

Mr. G. Barling (Leeds) suggested that in some of these cases the success of the operation might lie in the fixation of a previously loose kidney, owing to a consolidation of the perinephric tissue produced by the handling of the organ. He believed that relief of tension could be afforded by the operation, but he instanced a case of very severe congestion following on catheterisation where he could not hope for relief by such means; the extreme condition of vascular engorgement and extra-vascular extravasation would not allow of it. In such cases they must rely on medical means and wet cupping. In cases of marked hæmaturia where the affected kidney was detected by the cystoscope, bisection of the organ in the anticipation of malignant growth elicited no explanation for the bleeding; the organ was therefore sutured and returned with the result that for three years there had been no recurrence of the symptoms.

Mr. R. C. Chicken (Nottingham) controverted the usefulness of the operation on the grounds (1) that hæmorrhage in the kidney resulted in minute clots which were not removeable by any incision; (2) that it had been shown by the work of Moxon and of Johnson that the vascular supply of the kidney was very distinctly in connexion with that of the dorsal parietes, so that any good effect of kidney incision could be equally well produced by skin or lumbar incisions. Further, he had in a case of scanty bloody urine obtained complete cessation of the symptoms by repeated washing of the bladder.

Sir William MacCormac (London) proposed a vote of thanks to the President for the admirable paper with which he had opened a discussion of much interest.

Mr. J. Hutchinson, jun. (London), read a paper on

Operative Treatment of Renal Calculus.

He pointed out that the skilled use of the Roentgen rays has improved the treatment of this disease in many ways: (1) by affording precise indications for operation; (2) by showing the size, number, and exact position of the stones; (3) by making the operation simpler, more speedy, and safer than before; and (4) by revealing in some cases the presence of unsuspected stones in the opposite kidney, or proving that the pain had been misleading as to the site affected. The objections formerly raised to the use of the x rays were now practically removed. The photograph could be produced with such rapidity that the mobility of the kidney with respiration could be neglected; the best of his photographs had been produced by a 15-second exposure. He believed that the use of this means of diagnosis would abolish the custom of dragging out the kidney into the loin and the splitting of the cortex in search of stones, and further that there was less risk of overlooking one of many stones. He showed the safety of opening the pelvis of the ureter and removing stones directly therefrom, rather than indirectly through the cortex. He thought that in all cases where even small stones were seen to be present operation was indicated; their presence was a danger to the kidney and so to the life of the subject.

Mr. J. R. Morison (Newcastle-on-Tyne) cited a case where the symptoms were almost undoubtedly those of stone. Mr. Mackenzie Davidson could find no signs of calculus with the x rays. He (Mr. Morison) noted that when a stone was indicated by the shadow it might be held with certainty to be there, but an absence of shadow did not afford a negative certitude. He agreed that incision through the pelvis of the ureter was both preferable and safe. If the ureter was patent there was no risk of fistula.

The President repeated a question which he had put in The Lancet of February last as to the possibility of affecting the depth of the shadow of a stone produced by x rays by the colouring of the stone by the exhibition of drugs. He had seen stones deeply stained by the use of methylene blue for cystitis.

Mr. N. Bishop Harman (London) said that the experience of physicists was that the depth of the shadows obtained by the use of x-rays depended upon the chemical density only of the object interposed between the kathode and the sensitive plate. The heavy and dense metals and metallic salts were impermeable to the rays, whilst materials of lesser density, irrespectively of their colour, were to a greater or less degree permeable. It was not possible to affect the density of calculi by their colouration by the usual dyes; if they could be impregnated with heavy metal salts this could be done, but he doubted its possibility or utility in the human body.

Dr. H. Bramwell (Cheltenham) read a paper on

A Case of Moveable Kidney producing Stenosis and Constriction of the Duodenum by Peritoneal Bands.

The case supported his contention that a simple acquired moveable kidney was not a condition of slight importance, and that contrary to the case of floating kidney, where the organ formed for itself a channel under the peritoneum which allowed it to move without damage to the hollow abdominal viscera, the form of moveable kidney described carried with it its peritoneal covering, with the result that there was considerable dragging on the adjoining hollow viscera. The thickened bands thus produced were capable of seriously affecting neighbouring hollow organs, producing stricture of parts with consecutive dilatation of others. In this case spasm and stenosis of the pylorus produced fatal gastric dilatation with atrophy of the muscular coats of the viscus.

Femoral Hernia.

Mr. R. H. Parry (Glasgow) described a means of closing the crural canal from above, in place of the older method of closure from below, with which he had obtained excellent results. He maintained that by it there was left no cup-shaped remnant of the crural canal and the liability of damage to the femoral vein was excluded. The procedure might be summed up as follows:—1. A curved incision over the inner end of Poupart's ligament convex downwards, the flap was turned up and the region cleared until (2) Poupart's ligament was exposed. 3. The sac was then cleared and opened, its contents examined and if possible replaced. 4. An incision was made through the external oblique above and parallel to Poupart's ligament, and a similar division was made through the transversalis fascia. If it had not been possible to empty the sac it could now be emptied by manipulation above Poupart's ligament. Thus he had been able to relieve strangulated herniæ without cutting Gimbernat's ligament (an important saving). 5. A catgut ligature was now passed through the fundus and neck of the sack and through the conjoint tendon and transversalis fascia; the tightening of this ligature resulted in the drawing up of the crumpled sac beneath the belly wall. 6. A strong suture was carried by a sharp curved needle on a handle through the conjoint tendon and transversalis fascia at a point opposite to the outer margin of Gimbernat's ligament, passed horizontally beneath the muscle and fascia for about half an inch, and then brought through them. The inner end of the suture was now passed through Poupart's ligament, and both were brought out in the groin. Second and third sutures were applied in a similar way. The tightening of these sutures would draw the conjoined tendon and transversalis fascia over the crural ring as a curtain. The sutures could be tied so as to avoid pressure on the vein. The final stages were in the usual way.

Mr. Jordan Lloyd (Birmingham), deprecated the introduction of special and highly technical methods into these operations; further, he preferred to see the sac cut off, and silk ligatures used on.

Mr. McAdam Eccles (London) also agreed to the advisability of removing the sac or using silk sutures. He thought that the closing of the canal from above Poupart's ligament was to be preferred to closing it below, since he believed there was a lessened liability to recurrence.

Mr. W. H. **BROWN** (Leeds) read a paper on

The Prevention of Shock during Prolonged Operations.

He dwelt particularly upon those cases where operative relief was sought by the patient in the last stages of exhaustion, where the strength was so enfeebled that there was little or no hope of the shock of an otherwise useful operation being withstood. In such cases he had found that marked benefit might be derived by the transfusion of quantities of saline solution to five pints or so; this addition of fluid to the circulation so far restored the patient that the operation could be proceeded with with reasonable hope of success; the blood lost was not so much missed, and in some cases there was found a better pulse after a severe operation when performed under these conditions than at the beginning.

Mr. T. R. **JESSOP** (Leeds) said that he was satisfied as to the utility of the procedure, particularly if combined with the hypodermic injection of strychnine.

OBSTETRICS AND GYNÆCOLOGY.

WEDNESDAY, JULY 31ST.

The Presidential Address.

Dr. J. W. **BYERS**, Professor of Midwifery and Gynæcology, Queen's College, Belfast, delivered an address at the opening of the section upon

Puerperal Fever, Uterine Cancer, and the Falling Birth-rate.

He said: In 1847–56 the mortality from puerperal fever in England and Wales was 1·8 per 1000. It rose to 2·28 in 1875–84, and to 2 46 in 1886–95 The following figures (which I owe to the kindness of Dr. R. Boxall, who has taken such an interest in this question) give the most recent available statistics:

Year.	Deaths from puerperal fever.	Death-rate from puerperal fever per 1000 births.
1895	1849	2·0
1896	2053	2 2
1897	1836	1·9
1898	1707	1·8
1899	1908	2 0

Dr. John Tatham, Statistical Superintendent, General Register Office, has kindly supplied me with the following most interesting details:

Deaths of Women at all Ages from Puerperal Fever and other Accidents of Childbirth per 1000 Registered Births in England and Wales:—

1871–80	4 72
1881–90	4·73
1891-99	5 12

The following return showing the number of deaths in Ireland tabulated under Parturition (accidents) and Puerperal Fever I owe to the courtesy of Mr. R. E. Matheson, Registrar-General of Ireland:—

Years.	Total.	Death-rate per 1000 births registered.
1895	769	7·2
1896	679	6·3
1897	696	6 5
1898	560	5·3
1899	601	5·8

For the same years the deaths from puerperal fever for the whole of Ireland were:—

Year.	Rate per 1000 births.
1895	3 0
1896	2·3
1897	2 1
1898	1·7
1899	2·0

I am obliged to the Registrar-General of Scotland for giving me the following

Table Showing the Death-rate from Puerperal Fever in Scotland during the Five Years, 1895–1899.

Year.	Number of deaths.	Proportion in every 100,000 of female population.	Proportion in every 10,000 specified causes of death.
1895	253	12	62
1896	220	9	63
1897	205	9	52
1898	227	10	59
1899	214	10	54

We may contrast these lamentable statistics with the following returns for the last two years of the practice of the Rotunda Hospital, the largest lying-in charity in the three kingdoms:

Mortality at the Rotunda Hospital for the Years 1898–99 and 1899–1900.

—	1898-99.	1899-1900.
Intern maternity:		
Total cases	1591	1560
Total mortality	10	6
Percentage mortality	0 62	0 38
Mortality from sepsis (two of these admitted septic)	5	0
Extern maternity:		
Total cases	2183	2109
Total mortality	8	5
Percentage mortality	0·36	0·23
Mortality from sepsis	2	0
Total cases	3754	3669
Total percentage	0 47	0·27

For two years the total was 7423, and the percentage was 0·39.

These figures should make those of us who are teachers feel how great is our responsibility, and that our efforts should be redoubled in urging upon students the importance of regarding the process of labour as a natural one and not to be lightly interfered with unless nature herself should fail, and that if interference becomes necessary they should use exactly the same antiseptic precautions that they see employed in any gynæcological operation. It is by the observation of these two principles—the avoidance of meddlesome interference and by the rigid use of antiseptic principles—that we may hope that in the present century the occurrence of puerperal fever will eventually be as rare in private practice as it became

in the nineteenth century in

subject in regard to which, I

late ourselves is cancer of the uterus. How does it originate? Why is it so common? Nay, more, why (at least this is my experience) is it becoming more prevalent? These questions surely demand solution. I am reluctantly forced to agree with a statement made by a distinguished American *confrère*, Dr. Baldy, in a paper read before the Section of Gynæcology, College of Physicians of Philadelphia, Feb 21st, 1901: "Cancer affecting the cervix uteri is one of the most deadly diseases with which medical men have to deal. By far the largest proportion of these patients eventually die of cancer, be it from the primary lesion or from a recurrence. And this in spite of all that has been done for them either surgically or medically." No doubt some gynæcologists may say the explanation is that operation is not done early enough, but, as Dr. Baldy fairly asks, "What is sufficiently early?" Every gynæcologist of experience must admit that he or she has met with cases where recurrence took place rapidly in what seemed to be at the time of operation a most promising condition, while, again, women with extensive disease have remained well for years after operation. We have passed through the stages of vaginal and of abdominal hysterectomy for cancer of the cervix, but I ask, have we up to the present made much real progress? It is not the immediate results of the operation we want to know, it is the subsequent history of the patients. At the present time we can, unfortunately, suggest no other plan of treatment of cancer of the cervix except by operation, but surely we cannot boast much if the statement of Baldy is correct that the most recent statistics, those reported in Cullen's work on Cancer and the review of cases by Winter of Königsberg, show that in reality less than 0 per cent. of all patients applying for treatment of cancer of the uterus are saved by operation. The obvious lesson is that to ensure any real success we must urge on practitioners the enormous importance of early diagnosis, and that the one symptom which should always be regarded with suspicion is abnormal hæmorrhage. Any woman with abnormal hæmorrhage at any age, and especially if she is over 35 years, demands the most careful clinical examination. Let us hope for greater progress in the future.

Having glanced in what, I am afraid, is a very cursory survey at the progress of these subjects which specially concern us, let me turn to another question of the greatest interest to the State as well as to the medical profession. During the present year the public press has been calling special attention to the falling birth-rate. It would appear hat in England and Wales in 1861-71 the birth-rate per 000 was 34 8. In 1871-81 it was 34·7; in 1891 it was 31 4 er 1000; and since then it has steadily gone down until in the last year of the century, 1900, it was only 29 per 1000. In 1875 35 children were born in the United Kingdom for each 1000 of the population, while in 1900 there were only 29. In other words this means that for our population of 41,500,000 we are losing 249,000 children annually, and the birth-rate has fallen by 2 67 in the last 10 years. The actual increase of the population of England and Wales is due to the fall in the death-rate and the increase of immigration. We are thus rapidly in England approaching the condition prevailing for some time in France and America. It is not for me at present to discuss the causes of this declining birth-rate; rather my duty is to ask what remedy can we as medical men suggest to combat a state of matters which, from a national and imperial standpoint, must be regarded as most unsatisfactory. If fewer children are in the future to be born in this country, we must redouble our efforts to lower the high death-rate of infants, which during the first year of life amounts in England to 154 per 1000, by teaching the people to pay much greater attention to rearing their children properly.

Professor Byers concluded by impressing upon his audience the absolute necessity of examining patients expecting their first confinement as strictly and exhaustively as though for life assurance. He urged the importance of instructing impending mothers on all questions of diet and exercise, and deplored the fact that in Great Britain no enterprise was shown in the matter of supplying sterilised milk for infants.

The Causation, Prevention, and Treatment of Miscarriage.

A discussion on this subject was opened by Dr. PETER HORROCKS. President of the Obstetrical Society of London. The causation of miscarriage was classified as follows:—*A. Damage to the normal attachment between maternal and fœtal parts.*—(*a*) Accidental, such as injuries from hard work (lifting, strains, running and jumping), falling, blows, coitus, shock, fright, vomiting, coughing; surgical interference, such as operations about the vagina, cervix uteri, ovaries, and abdominal sections generally; passing instruments into the uterus, such as the uterine sound or dilators; and vaginal douching (*b*) Criminal, by the passage of a sound, bougie, curette, sharp instrument to rupture the membranes, tents, injection of fluid into the vagina or uterus, dilatation of the os uteri, application of caustics to the os uteri and within the canal of the cervix; packing the vagina, dilating and trying to set up reflex action in the uterus; drugs, such as purges (especially aloes), savin, ergot, lead, mercury, arsenic, carbonic oxide, and carbonic dioxide as in asphyxia; and violence, such as jumping, dancing, riding, rowing, falling, blows, and tight bandaging of the abdomen. (*c*) Disease of neighbouring parts, such as fibroids, parametritis, perimetritis, tubal diseases, ovarian diseases, tumours or blood-clots in the pelvis, contracted pelvis, tumours in the abdomen, tight lacing, and rectal diseases. (*d*) Artificial, when abortion is scientifically induced by means of bags, such as Barnes's, De Ribes's, Horrocks's; sound, dilators, bougie, tents, sharp instruments rupturing membranes, curette; drugs, such as ergot, digitalis, savin, cantharides, quinine, gossypium, lead, aloes, purgatives; and douching, dilatation of the cervix uteri, and dilatation of the vagina. *B. Fœtal pathological conditions.*—Syphilis, malformation causing death of the fœtus, spina [illegible] cord round the neck, too short a [illegible] the placenta, carneous mole, hydatid mole, fatty [illegible] tion, excessive or scanty liquor amnii, [illegible] low vitality, imperfect fertility from de[illegible] ness, extreme youth or age [illegible] father), inflammation, œdema [illegible] diseases of the chorion, amni[illegible] kidney, liver, genitals [illegible] of the rupture of the membranes. *C. Maternal diseases, gen*[illegible] *local.*—Fibromyomata, displacements (especially [illegible] sion and retroflexion), syphilitic endometritis, [illegible] hæmorrhage into the placenta, carneous mole [illegible] heart, lungs, liver, kidney—eclampsia; chorea, [illegible] blood diseases, jaundice (acute yellow [illegible] placenta prævia; zymotic diseases, especially [illegible] scarlatina, and typhoid fever, which destroy the [illegible] toxæmia, pyrexia, or hæmorrhage into the placenta [illegible] rhœa gravidarum, catarrhal endometritis, [illegible] habit (menstrual nisus), cancer, apoplexy; fissure [illegible] cervix, deep lacerations, patency of canal [illegible] lower zone of uterus, pyrexia. [illegible] anything causing it to cont[illegible] sitz-baths, and tooth extrac[illegible] riding, dancing, cycling, [illegible] lifting, walking too fa[illegible] dogs, operations, tig[illegible] ecbolic drugs, over-lact[illegible] heated rooms, bad vent[illegible] late hours. The things [illegible] inflammations, displacem[illegible] flatulence and colic. The [illegible] syphilis, bad health, weakne[illegible] laceration of the cervix, and [illegible] carriage was considered under [illegible] miscarriage was (*a*) avoidab[illegible] features of treatment were [illegible] ergot, or other ecbolics—[illegible] unavoidable (here the [illegible] means of tampons or gau[illegible] rupture of the membranes, and the clearing out of the uterine [illegible] complete (here delivery should be completed by the tampons or packing or by clearing out the uterus [illegible] pletely).

Dr. AUST LAWRENCE (Bristol) said that proper [illegible] depended on correct diagnosis and a very important [illegible] was the diagnosis between threatened abortion [illegible] uterine pregnancy. Broadly, he laid down the [illegible] much hæmorrhage and little pain [illegible] miscarriage, whilst scanty [illegible] pointed to the extra-uterine [illegible] When [illegible] was inevitable the sooner the uterus was [illegible] In hospital this should be done deliberately [illegible] anæsthetic; in private practice it was often better [illegible] first instance to pack the cervix and vagina with iodoform gauze. He deprecated the use of the curette, [illegible] that the finger was sufficient. Complete dilatation of [illegible] cervix was of the utmost importance, inasmuch as [illegible] septicæmia followed it was nearly always the result [illegible] incomplete dilatation.

Dr. A. J. SMITH (Du[illegible] abortion that needed no [illegible] pain, slight hæmorrhage and no dilatation of the os. [illegible] requiring interference were those with much pain, [illegible] of the cervix and protrusion of the ovum. The best [illegible] in the prevention of miscarriage were cannabis indica [illegible] opium. He did not approve of ergot, because he [illegible] that if enough were given to arrest hæmorrhage [illegible] itself induce abortion. If inevitable the ovum should [illegible] separated with the finger; to remove the ovum a[illegible] practice consisted in removing the finger and seizing [illegible] uterus bimanually, when the ovum would be found [illegible] out. It was sometimes a matter of difficulty and yet [illegible] importance to determine whether or not the ovum [illegible] actually been expelled. In this connexion it was useful [illegible] note that before expulsion the internal os was [illegible] and the external os closed; whilst after expulsion [illegible] internal os was closed and the external os open.

Mr. HAWKINS-AMBLER (Liverpool) referred to the [illegible] ment of constipation, which was often a very difficult [illegible] in these cases, as too much purgation might lead to [illegible] which they wished to avoid. Packing with gauze was [illegible] after clearing out the uterus, because [illegible] shreds, &c., might be retained and the gauze [illegible] them away.

Dr. J. A. Lycett (Wolverhampton) insisted on the part played by excess of alcohol, [illegible] also in causing deterioratio[illegible] survived. With regard to [illegible], he thought that a medical man was not necessarily to blame if this occurred, but he would be to blame if he overlooked [illegible] Dr. Lycett showed an [illegible] to retroversion of the gravid uterus as a cause of abortion; in some cases the reposition of the uterus and insertion of a well-fitting Hodge failed to avert the miscarriage. He spoke also of the tendency to abortion in cases of heart disease. In one case of this kind he kept the patient absolutely in bed and ordered daily massage, with the result that she went on to full time. In treatment where there was hæmorrhage without pain he gave ergot in from five to 10 minim doses every hour; opium might be given at the same time if necessary. If there were pain as well as hæmorrhage he did not give ergot. In cases of unavoidable hæmorrhage he advocated the complete clearing out of the uterus combined with curetting of the endometrium under anæsthesia He used a flushing curette with perchloride in the strength of 1 in 2000. In some hundreds of cases in which he had adopted this treatment he had never had either hæmorrhage or rise of temperature following the operation.

Dr. Inglis Parsons (London) expressed his belief that a woman who was fairly healthy and sound could do almost anything in the way of exercise or travelling without fear of aborting. Among antiseptics for use in cases of surgical interference he specially recommended the use of chinosol. An excellent sedative in cases of threatened, but not inevitable, abortion, was viburnum primifolium.

[illegible] king [illegible] gina. [illegible] was [illegible] ervix [illegible] she thought it best to avoid the use of the volsella when the cervix had to be packed.

Dr. F. W. N. Haultain (Edinburgh) dwelt on the importance of full dilatation of the cervix before any attempt was made to extract the fœtus; sometimes the body of the fœtus was drawn through and the head left behind because the orifice was too narrow. If the dilatation was insufficient it was better to pack the cervix with gauze and to wait.

The President remarked that the syphilitic factor was an important one, although the part it played had, perhaps, been overstated by continental writers, who attributed to this cause 60 per cent. of abortions. Repeated abortions were specially apt to be due to this cause. Treatment should be given to both parents.

Dr. Horrocks briefly replied.

Deciduoma Malignum.

Dr. Peter Horrocks read the notes of a case of this kind and showed the specimen, together with microscopic sections. The patient thought that she had miscarried and was losing much blood. Examination revealed a growth and hysterectomy was performed. The patient made a good recovery from the operation but died some two months later from secondary deposits. Unfortunately no necropsy was allowed.

Cæsarean Section with Notes of Three Successful Cases.

Dr. Munro Kerr (Glasgow), in his paper, pointed out that the operation had been performed in the Glasgow Maternity Hospital between 60 and 70 times since April, 1888; and that in the cases that had proved fatal, with two or three exceptions, the cause of death had been septicæmia; further, that in the majority of cases the infection was through the vagina and cervix, and not through the abdominal wound. He therefore laid great stress on the preparatory cleansing of the vagina by thorough cleansing with lysol He did not draw out the unopened uterus through the abdominal wound The opening in the uterus was in every case longitudinal and in the middle line, the bleeding in cutting through the wall being controlled by the vulcanite ring recommended by Cameron. After extraction of the child the uterus was firmly grasped by the assistant to control bleeding, elastic tubing was not used for this purpose. The conservative operation was done in each case, the uterus being left, but the patients were sterilised by tying the Fallopian tubes in two places and dividing between the ligatures. In each case labour was in progress, and in two had advanced considerably before the operation was commenced. After giving the notes of three cases Dr. Kerr remarked that the safety with which Cæsarean section could now be performed was such that in cases of pelvic deformity they were now hardly ever justified in destroying a living child by craniotomy. The only circumstances where such operations were permissible were where fruitless attempts had been made to extract the child with forceps or version, from ignorance or miscalculation of the extent of the pelvic deformity; where the mother's condition was such as to preclude abdominal section; and where the child was the subject of hydrocephalus or some other extreme malformation or was dying. That the pregnancy was illegitimate could not be considered as affecting the indications of the operation. With such a circumstance they dare not concern themselves. Dr. Kerr did not consider that there were valid grounds for preferring supravaginal amputation to the conservative operation. Nor did he endorse the transverse fundal incision recommended by Fritsch. It was, however, important that the longitudinal incision should not be carried too low. In all the cases the placenta was situated on the posterior wall of the uterus and separated immediately after the birth of the child

In the discussion on this paper Dr. Purslow (Birmingham) remarked that he considered it an advantage to make a longer incision and to draw the whole uterus out of the wound before opening it.

Dr. William Duncan advocated the operation of removal of the uterus. In all his cases he had found the placenta situated in front.

Mrs. Scharlieb (London) said that in the cases which she had seen the placenta was always behind. She had employed the straightened-out Hodge recommended by Cameron; but it was of little use except when the child was lying with the back anteriorly, for otherwise no pressure could be exerted.

After some observations by Dr. Horrocks, Dr. Munro Kerr replied.

Mr. Hawkins-Ambler read a paper on Shock in Abdominal Operations, and Dr. William Duncan expressed regret that the lateness of the hour precluded a proper discussion of this admirable paper.

STATE MEDICINE.

Wednesday, July 31st.

The Presidential address.

The President (Mr. Shirley Murphy, London), after referring to progress in sanitary matters, said that each [illegible] better opportunities of [illegible] the laboratory. There [illegible] if the Notification Act was to be fully utilised. Valuable material already existed for the study of the behaviour of infectious diseases and there should be some classification on a uniform principle. It was hoped that the time was not far distant when it would be possible to take stock of industrial diseases.

The Relation Between County and District Sanitary Administrations.

Dr. F. T. Bond (Gloucester) opened the discussion on this subject. He said that any form of sanitary administration without a medical officer of health was, to use a well-worn simile, like the play of *Hamlet* with the *rôle* of the Prince of Denmark omitted Where the appointments of sanitary inspectors were filled by thoroughly competent men a single medical officer of health could superintend efficiently a far larger district than was possible where he was unable to depend on his inspectors. County councils should have the same freedom of combination with one another that was possessed by the district councils. The Public Health Act allowed district councils within or without the same county to combine for various purposes, including the appointment of a medical officer of health, and the same power should be given to counties. Dr. Bond then proceeded to discuss whether it was expedient as a general principle that the medical officer of a county council should hold at the same time any appointment under a district council in that county In his opinion, the work required the intelligence and experience of a trained expert, and whether that expert held the position of a county medical officer or of an officer to a combination or to a single district was not of the least importance What was of importance was that he should be competent for the work, and the objection to a district medical officer reporting on his own annual report as a county official was founded on an erroneous view of the work involved. Wherever combined districts existed in any counties they should be utilised as the basis on which they could most conveniently and economically erect a well-adjusted county sanitary administration. Amongst the duties which would ere long probably be imposed on sanitary authorities would be the superintendence of vaccination and this would at once make it imperative that every county council should appoint a medical officer of health. The plea that it was of no use for these councils to make such an appointment until they were invested with fuller sanitary powers was met by the reply that county councils could hardly expect that their sanitary powers should be enlarged until they showed that they had made an effort to use those with which they were already invested.

After some remarks by Mr. G. H. FOSBROKE (Worcester),

Dr. J. LLOYD ROBERTS (Colwyn Bay), said that in North Wales there was but one county and in South Wales there was but one that had officers of health. Many English counties were in the same position. It was unnecessary to enlarge upon the great losses to the public health entailed by the failure of these many counties to establish committees and officers who would be the connecting links between the county and the local administrations. Many localities could be called to mind as being as insanitary at the present time as they were when the Public Health Act came into operation in 1875. There were localities in which sewerage and water-supply schemes had been propounded for more than 20 years which were as far from accomplishment now as ever they were. Where Local Government Board inquiries had been held on epidemics nothing had been done after the exciting cause had passed off. District councils were responsible for these omissions and shortcomings and the causes were fear of putting the parish to expense and personal dread of loss of popularity and consequent loss of a seat on the council. The Local Government Board spasmodically and at long intervals wrote to a district council to ask what action was being taken upon a certain matter and they seemed to be contented with receiving a courteous but evasive reply. District councils escaped taking responsible action by sheltering themselves behind the Local Government (Parish Councils) Act 1894, which required *notice* to be given of sanitary proposals to the parish councils concerned. Parish councils based their ideas of public health requirements upon finance rather than upon necessity. A scheme for sewerage or for water-supply had to go through a parish council not for approval but for information and then to the Local Government Board for approval and permission to raise a loan. In the matter of finance there was no such want of uniformity. Government auditors looked properly after the accounts and over each and every authority and the various members thereof there was always the fear of this official auditorship overhanging, lest by any mistake or mischance a surcharge should be made upon the individual who wrongly signed a cheque. It was clear that, as in the case of the Infectious Diseases (Notification Act) which had been made compulsory everywhere, all county councils that had not appointed medical officers of health should be called upon to make such appointments, and county councils might be endowed with the powers of the Local Government Board. In this manner county and district sanitary administrations could be brought into relation.

Municipal and County Laboratory Work.

In his absence a paper by Dr. E. C. SEATON (London) was read by one of the secretaries. Dr. Seaton's opinion was that laboratory work entered more than ever into the daily routine of the public health and sanitary departments of most municipalities. After a full retrospect of the facts of the case the scope of sanitary analyses was next dealt with in the paper. In every large town there was a demand for bacteriological examinations for diagnostic purposes in aid of the general practitioner and also for hospital purposes which might be provided at a central bureau connected with the municipal offices. The first object of the sanitary authority should be to repress injury to health and not to allow this to become subordinated, as it had been for some time past, to the detection of a certain kind of commercial fraud. The concentration of laboratory work was then discussed by Dr. Seaton, who gave details of the county laboratory of Worcestershire, where the analytical chemist, Dr. Duncan, conducted the diagnostic examinations for diphtheria, empyema fluid, tubercle, &c.

Mr. HENRY MAY (late medical officer of health of Aston Manor) considered that no injustice was done by a county medical officer of health being also district medical officer of health.

Mr. T. W. H. GARSTANG (Bowdon, Cheshire) advocated "security of tenure" for medical officers of health. He thought that weekly notification of infectious diseases was a matter dependent on local conditions.

Dr. E. J. SLADE-KING (Ilfracombe) said that Parliament should make weekly returns absolutely compulsory. If parish medical men were life officers it was much more important that medical officers should be.

At this stage of the discussion Dr. J. GROVES (Carisbrooke, Isle of Wight) moved, Dr. SLADE-KING seconded, and Mr. HERBERT JONES (Hereford) supported, the following proposition, which was carried later in the proceedings:—

> That having regard to the paramount importance to the interests of the public [illegible] tenure of office of sanitary officers the State [illegible] express their approval of the action of the cou[illegible] in Parliament to that end and their thanks for the same.

Alderman WALTER SMITH (London) advocated that bacteriological examinations should be undertaken by sanitary authorities for medical men gratuitously.

Dr. A. K. CHALMERS (Glasgow) said that in his district the bacteriological work was done gratuitously with satisfactory results.

The PRESIDENT believed that the ultimate solution of the problem of the relations between the county and district medical officers of health would be found in the appointment of both by the county council.

Dr. BOND, in winding up the discussion, said that it was desirable to have as much elasticity as possible in this matter and that the requirements of efficiency should not impose undue pressure on county finances.

Dr. D. S. DAVIES (Bristol) read a paper on

Plague and its Prevention as a Disease Communicable from Animal to Man

and at the conclusion he made the following motion which was seconded and carried:—

> That this meeting considers the time has come when the question of dealing with ship-brought plague deserves the attention of the Government, with the view of securing an international agreement whereby merchant vessels shall take the necessary steps for the destruction of rats on board before loading and upon discharge, and, in addition, for the adoption of uniform steps to prevent intercommunication during loading and discharging between ship and shore rats.

PSYCHOLOGICAL MEDICINE.

WEDNESDAY, JULY 31ST.

The Presidential Address.

Dr. J. B. SPENCE, resident physician and superintendent, Staffordshire County Asylum, Burntwood, delivered the following introductory remarks at the opening of the section:—

Asylum Administration and Nursing.

Dr. Mercier, in his well-known crisp and incisive manner, has in the last number of the *British Medical Journal* for 1900 given a brief, instructive, and interesting account of the position of affairs in the lunacy world at the commencement of the last century, and it would well repay the labour involved and the time occupied if one had the opportunity to enumerate in detail the various discoveries, improvements, and legal enactments which have so advantageously changed the treatment of the mentally afflicted since that period. Not only, however, were the insane subject to very terrible and inhuman treatment at the commencement of the last century, but in many other directions also the condition of the people was practically in a state as unsatisfactory. Picture to yourselves the prisons of those days—the dens to which debtors were relegated, the condition of the poor in their own homes, the monstrosities practised in the name of justice, when men were sentenced to death, and not only sentenced but in some instances actually hanged, for offences which in these happier days would be considered as severely punished by a few months, or at the most years, of imprisonment in establishments which, when contrasted with the prisons of a century ago, may fairly be said to have made as great an advance as that which has taken place in our asylums or other public hospitals. For the marvellous progress that has marked the past century and has rendered the Victorian era a golden one we should not rest content with being merely grateful, but should endeavour as far as lies in our power to maintain and promote all means which tend in the direction of useful progress, and so continue the great work which has made the names of Tuke, Conolly, the Browns (father and son), Bucknill, Maudsley, Clouston, and many others honoured and glorious in our specialty. I heard it said not long ago that there was a *feeling* abroad in favour of lay management of our large asylums. Well, to those of us who have lived long enough this is nothing new. Ideas occur in cycles, and what to the experienced is but the repetition of an oft-exploded theory comes to those who are new to the subject and who have not given it much consideration as something which, to put it at its lowest, merits at least a trial. It does appear to me that in few other positions is the combination of the medical man with the good organiser so necessary as at the head of an establishment in which the treatment of the inmates is not purely medical or purely reformatory or merely curative, but where many methods must be employed if ultimate success in dealing with the variety of types which come under our care is to be looked for. It is in this connexion that I regret the establishment of the huge asylums to which unhappily use is accustoming us. In the medium-sized asylum there is just that amount of work which any man who is worthy of his position should be able to supervise with due attention to the various departments into which the establishment must necessarily be divided, and where the one governing mind can so utilise the means of treatment placed at his disposal that whether the individual patient—known to the chief by name, by disposition, in his family relationships, in his special characteristics, and in his necessities—requires medical or moral treatment, the care of the sick-room or the exercise of the garden or farm, the quiet of the cosy ward or the stimulating effect of the workshop, each can be brought into play without the risk of producing that friction which practical experience has shown to be not infrequently present when more than one controlling influence is in operation. As a question of expense, I have yet to learn that the medium-sized asylum is more costly in its management than the large establishments which, while they excite the wonder of the inexperienced, produce only feelings of regret in the minds of those who have to govern them. Nor have I had it proved to me that better results have been produced either in the treatment of the insane individual himself with regard to the promotion of his recovery, the increase of his comfort when in fair bodily health, or his treatment when attacked by illness, physical or mental. The feeling of consternation that is abroad in connexion with the necessity for still further provision for the insane will have to be dealt with and one cannot resist the conviction that the time has come when some change in the classification of our patients might well be attempted. There is ample scope, I feel sure, for hospitals for the insane to which only paying patients at low rates should be admitted and there is a large class of demented lunatics and unteachable imbeciles in asylums for whom plain housing and plain dieting might well answer. There are also epileptics and imbeciles in workhouses who should no longer, or only for the short time that is required to provide other abodes for them, be detained in places which, on the showing of many speakers at a recent Poor-law conference, are quite unsuited for the care and treatment of such cases. I know full well that there is a strong feeling against the herding, as it is called, of a number of imbeciles and demented people together. I have heard not so long ago a very forcibly-expressed opinion that it would be an improper thing to remove the demented from our asylums, as the prospect of recovery should never be lost sight of even in the most apparently hopeless cases, but with all respect for the opinion of such a distinguished member of our specialty as Sir James Crichton Browne, I cannot think that for the sake of the very occasional case of recovery to which he referred in his admirable address to the Asylum Workers' Association we should be deterred from providing good and proper but comparatively inexpensive accommodation for the class of patients to which I allude. It is not my intention for one moment to suggest that the chronic dement in the counties should not receive the same amount of care that is given to the corresponding class for whom the Metropolitan Asylums Board is responsible. What I urge is that some such accommodation and treatment should be provided in the counties as are given in London, thus relieving the acute asylums and enabling them to carry out the work for which they should be, in my opinion, reserved. There is the difficulty, for the small counties that an institution common to several would probably be required owing to the few cases each of these counties would have to provide for. It has been said also that even the individual lowest in the scale of mental degradation can appreciate the bright and comfortable surroundings of the average county asylum. But when all is urged that can be brought forward to support this side of the question, I shall still hold the opinion that while no expense should be spared to provide the necessary appliances and the most favourable environment for the curable, yet in a distinctly appreciable proportion of the incurably insane and the mentally deficient a kindly, judicious, and truly philanthropic system of treatment might be adopted without loss of benefit to the class in question and at a much reduced cost to the long-suffering ratepayer. As to the form in which accommodation should be provided for those suffering from mental disorders of a curable nature, I am delighted to think that the trend of educated opinion in this country is in favour of segregation, and we are all looking forward with interest to the result of the experiment which has been taken in hand by the East Sussex County Council and by the authorities whose duty it is to provide accommodation for the insane poor of Edinburgh and Aberdeen. Dr. Spence concluded by referring to the progressive work of the London County Council at the Claybury Pathological Laboratory and pleaded for the systematic education and training of asylum attendants.

Dr. W. FORD ROBERTSON (Edinburgh) opened a discussion upon

The Rôle of Toxic Action in the Pathogenesis of Insanity.

He said that whatever else mind might be it was in the first place a product of the functional action of certain of the cerebral neurons. For the normal manifestation of this functional action three factors were essential—namely, (1) integrity of the anatomical elements which form the physical basis of mind (cortical neurons); (2) suitable nutritional conditions for these anatomical elements; and (3) those sensory impulses which, commencing to impress the anatomical elements at an early period of life, gradually endow them with their special functional powers and of which the almost continual stimulus is required in order to call these powers into action. Morbid mental action might primarily depend upon a fault on the part of any one of these factors. He discussed the importance to be attached to inherent and acquired faults on the part of the cortical neurons, to the effects of sensory impulses, and to unsuitable nutritional conditions. The last might consist either in a deficiency of certain nutritive materials required by the nerve-cells or in the presence of chemical substances which were taken up by the cells and then disordered their metabolism. Any such substance was a toxin. He contended that by far the larger proportion of inherent predisposition to insanity was not based upon any condition that could rightly be called degenerative, but depended merely upon the presence of one extreme of those wide though limited differences that individuals exhibit in the reactive qualities of their nerve-cells to various forms of toxic action. He specially insisted upon the importance of the indirect action of toxins upon nerve-cells by causing disease of their nutrient vessels. The various toxic conditions which tended to affect

tract. He maintained that various forms of toxæmia of gastro-intestinal origin were the chief factors in the pathogenesis of a large array of acute and chronic diseases, including several forms of mental disease. These diseases comprised the various manifestations of arterio-sclerosis, a large proportion of cases of senile insanity, general paralysis, locomotor ataxy, chronic alcoholic insanity, dementia præcox, idiopathic epilepsy (as the determining cause of the fit), and most cases of acute and chronic mania and melancholia and of chronic Bright's disease. The large majority of cases of insanity were not primarily diseases of the brain at all, but were dependent upon the action of toxins derived from elsewhere, which affected the functional activity of the cortical neurons by disordering their metabolism and often permanently damaging and even destroying large numbers of them. He endorsed the opinion of Dr. Mercier that "insanity is a disease of the whole organism which can only be properly understood and properly dealt with when so regarded." Not until such views were generally recognised by alienists and gave direction to their investigations into the nature of insanity, would any important further advances be made towards those great preventive and therapeutic measures that were, beyond all questions, attainable in this department of practical medicine.

ANATOMY AND PHYSIOLOGY.

Wednesday, July 31st.

The Presidential Address.

Dr. A. Macalister, Professor of Anatomy in the University of Cambridge, opened the work of this section with some remarks on

The Anatomy Act and the Teaching of Anatomy.

He said: One of the consequences of the specialism characteristic of the modern development of the sciences ancillary to medicine is that many of the more interesting new advances in these branches of knowledge are not of much interest to the practitioner. This is particularly the case as regards anatomy. The growth of that science of late years has been greatest on its morphological side, and it must be confessed that as yet the practical applications of these modern extensions are not obvious on the surface. I do not say that they are quite devoid of practical interest, for it is our experience that the scientific curiosities of one period are the fundamental principles of the necessities of the next. Neither do I mean to say that practical anatomy has ceased to be the groundwork of the studies of the medical student. Present-day surgery, which boldly adventures into regions of the body whereinto our predecessors dared not enter, requires those who practise it to possess an intimate knowledge of parts of the body which a century ago were only regarded as of speculative importance. The knowledge of the minute details of the relational anatomy of the abdominal organs and of cranio-cerebral topography are necessary parts of the education of the modern surgeon, as is that of the complex system of nerve paths and neuron groups an essential element of the knowledge of a modern physician. The work of the dissecting-room and histological laboratory bulks as largely as ever in the curriculum of the twentieth century medical student, and as with the increased burdens which a wider range of education has made essential the medical student cannot spend quite as much time as heretofore in anatomical study it behoves us to see that these departments of our medical schools are as perfectly equipped as possible.

Now it happens, from the nature of the case, that the study of practical anatomy labours under difficulties which do not beset any of the other fundamental sciences. The professors in the other departments can in open market procure the materials for the supply of their laboratories in a way which the anatomist cannot. It is true he can buy bones, models, and casts, but they are only a very small part of his equipment; it is impossible to teach anatomy without an adequate supply of bodies for the dissecting-room, and every year the problem of that supply is becoming more acute. This growing difficulty depends on several conditions, some of which are inseparable from the material and intellectual progress of the age. Better wages and improved education have raised the worker in the community to a higher and more independent and satisfactory position. The proportion of those who are driven by stress of want into the State-provided asylums for the destitute is diminishing. Improved postal and telegraphic communication enables the relatives of any who, from their faults or misfortunes, have become submerged to receive notification of their whereabouts, and in the event of their death increasing facilities of transport enable them to claim the bodies far more easily than was the case half a century ago.

It is not, however, the lack of available material that is as yet the chief difficulty. We are a long way off the condition of social and ethical perfection in which there is no submerged fraction of the population, and while humanity continues as it is the poor we shall ever have with us, and among them there is little prospect of the disappearance of the class who by their own vices or follies have sundered themselves from their connexions and who find ultimate refuge in the State-aided asylums. Why, then, should there be the difficulty? How has it come to pass that with no great diminution of the number of unclaimed bodies many of the London medical schools were starved of their needful supply last year? How, also, does it happen that in the records of the advance of anatomical science this country is distinctly falling behind its continental neighbours? A foolish piece of insular prejudice has attached a sense of deprecation to the term "made in Germany"; but, as in other sciences, so in anatomy. It is to the article made in Germany we must go if we want to find the most trustworthy and accurate anatomical investigation and the results of the most patient work. It is to German laboratories our men must go if they wish to be trained for research and to find the facilities for original work. It is not that our students are inferior in ability or less zealous in the pursuit of knowledge, but it is largely a question of lack of material, as in our schools nearly all the available material is ear-marked for elementary teaching.

The reason why the condition of things is so different in Germany is this: that there the law of the land makes provision for anatomical teaching. The unclaimed bodies of those persons who die in any public institution are *ipso facto* sent off to the university of the district. A similar law exists in Russia, Austria, and France. In this country there is no provision whatever made by law for anatomy. It is left to the professor of anatomy to endeavour to obtain what material is wanted. In my recently published Memoir of Professor Macartney I have dealt at some length with the subject of anatomical legislation in Great Britain, so I need only indicate one or two of the points in the law which affect the teaching of this subject. There is one Act of Parliament, c. 75 of the 2 and 3 William IV. passed in 1832. This Anatomy Act is simply of a permissive nature, one which neither provides nor even suggests any method whereby bodies can be procured. It only permits any medical man being licensed by the Home Secretary to practise anatomy provided he practises it in a licensed place. It requires that the Home Office must be notified of the receipt of a body within 24 hours of its arrival, and that a medical certificate of the cause of death must be sent with the notification. It further requires that the body must be buried with whatever religious rites are usual in the particular denomination to which the deceased belonged, and in a public cemetery, and that the formal burial certificate must be lodged in the Home Office at or before a specified date. Under these conditions a medical man is not liable to prosecution for practical anatomy. Strangely enough, the Act provides no penalties for breaches of it, nor is there any machinery for prosecuting those who infringe it. The Act empowers the Home Secretary to appoint inspectors, but says nothing whatever as to their duties or authority; and, although they are supposed to be endowed with mysterious powers, it is not from the statute that they derive such, if they really possess them.

So far the legislation only restricts the practice of anatomy. Before the Act was passed there was nothing to prevent any man from dissecting a body anywhere, so long as the act was not capable of being construed into a scandal *contra bonos mores*. Its only positive provision is that it declares the right of anyone having legal custody of a body to hand it over to the licensed anatomist not sooner than 48 hours after death. It does not define what legal possession means, and, considering that it has been decided by more than one judicial authority that a corpse is not property and cannot be dealt with or bequeathed by deed or will, it is difficult to see how one can possess what is not property. The permission granted in the Act is no new thing; from the beginning of systematic medical training in England in the thirteenth century the right to dispose of a body by those in whose possession it was has been unquestioned. The Act therefore gives no power which did not exist before. The result of the Act simply is that the anatomist is made to share with the publican and the pawnbroker this distinction—that he cannot practise his craft except on licensed premises, he himself also being licensed. He is not in any way helped forward towards his supply. He is left to himself to seek out those that have cadavera in custody, and is not aided in his efforts to persuade them to hand them over to him. In practice it comes to this—that the anatomist seeks the Poor-law guardians and endeavours to obtain his supply from them. Now, Poor-law guardians are periodically elected. The constituency returning them is wide and the franchise qualification minimal. The office is much desired by a considerable section of the community and hence the elections are often contested. The Englishman is a sentimental person, and those seeking his vote can gain the interest of the elector in no more sure way than by working on his feelings and sympathies. Experience has shown that there are few ways in which an independent guardian can imperil his seat more certainly than by voting for the *sending of unclaimed bodies to the anatomy school* The anatomist in consequence looks forward with anxiety to each periodical election of guardians in any union in which he has succeeded in persuading the majority of the guardians to grant him a supply Indeed it seldom happens that a re election passes without some attempt being made in the interest of sentiment to stop the sending of subjects for dissection Professor Macalister concluded by detailing his personally unpleasant experiences in dealing with the guardians and expressing his belief that no measure of improvement may shortly be expected

TROPICAL DISEASES

WEDNESDAY, JULY 31ST

The Presidential Address

Major RONALD ROSS I M S (retired) Lecturer in Tropical Medicine University College Liverpool was unable to deliver his presidential address to the section in person being abroad. His address which was read for him was as follows —

I have great pleasure in being able to record for the last year a general and perhaps unparalleled advance in our knowledge regarding tropical diseases

Yellow fever —The discovery of at least one mode of infection in yellow fever—a discovery of the highest importance to mankind—emanates from America For some time past several of our American colleagues stimulated by recent observations in connexion with malaria have sought an experimental verification of the hypothesis of Finlay and others that yellow fever also is communicated by the bite of gnats Insects fed on patients were subsequently induced to bite healthy persons who volunteered for the experiment. The results were negative until the gnats were kept for an interval of 12 or more days between the two operations Success was now immediate Dr Reed Dr Carroll and Dr Agramonte record in their last report that out of seven non immune persons subjected by them to the bites of infected mosquitoes six yielded undeniably positive reactions At the same time seven non immunes whom they endeavoured to infect by means of the fomites of patients under peculiarly favourable circumstances remained in every case free from the disease The experiments were conducted under the most stringent scientific conditions Although the mosquito theory of yellow fever does not possess the parasitological basis of the mosquito theory of malaria yet the differential observations of Reed Carroll and Agramonte are of a nature to leave no doubt concerning the soundness of their conclusions Some of the tests have involved great heroism on the part of those who were subjected to them. Since the death of Dr Jesse W Lazear we have to deplore that of Dr Walter Myers, one of our most promising young pathologists, who lost his life from yellow fever when on a deputation from Liverpool to study that disease If the pathogenic organism of yellow fever, hitherto undiscovered prove to be a vegetable organism, the fact will suggest that transference by suctorial insects and arachnids with which we are already so familiar in the case of animal parasites may be no less common in the case of vegetable parasites *A priori* there is nothing improbable in the view that suctorial insects may become generally infected by blood containing schizomycetes which may next find their way by route of the insects' salivary glands or otherwise into a fresh host. There are certainly some epidemiological facts which suggest the possibility of infection by gnats in undulant fever and perhaps leprosy and by other vermin in relapsing fever typhus fever and perhaps several skin diseases

Ankylostoma duodenale —Another important advance is contained in the confirmation of Giles's life history of the ankylostoma duodenale by Annett—details of which will shortly be published These observations throw a vivid light on the route of infection adopted by these dangerous and widespread parasites

Undulant fever —Owing to observations made by Wright on the serum reaction in undulant (Malta) fever, this disease has been shown to exist in India Hong Kong the United States the West Indies and Brazil—a most important fact in connexion with the great subject of tropical fevers

Malaria —The recent advance in our knowledge of malaria has been well maintained by numerous observers The practical side of the mosquito theory, which at once became predominant after the determination of the life history of the parasites has been energetically treated by Koch and his assistants who have successfully dealt with malaria on a large scale by means of quinine Similar work has been performed with success in the United States and, according to reports in Italy In British possessions isolated efforts to deal with malaria according to the new principles have been made by Sir William McGregor and Strachan at Lagos, and by Thomson and Young at Hong Kong , but the country generally has not adopted an intelligent attitude in this connexion. On the other hand British workers have closely studied details of the malaria question in many parts of the world. I must refer especially to the good work done in Central and West Africa by the Malaria Commission of the Royal Society and to an admirable sanitary survey of Nigeria made by the Liverpool expedition during the last year Direct cultivations of the parasites have been reported by Daniels, Ziemann van der Scheer and van Berkelom and Woldert in various countries—all in anopheles, while Manson has completed an interesting crucial experiment for the popular demonstration of the theory by infecting healthy persons (T Manson and Warren) in London by mosquitoes brought from Italy, and by simultaneously preserving others (Sambon and Low) in health in the Campagna in a mosquito proof house Nuttall and Shipley Christophers and Dutton have closely examined the anatomy of gnats Nuttall Cobbett, and Strangeways Pigg have made interesting researches on anopheles in England in which by the way, cultivation experiments have hitherto failed Gosio Giles Reinhold Ruge Fearnside Neveu Lemaire and others have done useful work on the subject in many directions It remains however a matter for regret that stronger efforts have not been made to determine the reason why individual gnats of an amenable species so often resist infection Until this difficulty is cleared away negative experiments with culex cannot be entirely convincing

Since the last annual meeting of the Association the mosquito theory of malaria has received the highest scientific acceptance in the address of the then President of the Royal Society, Lord Lister

Filariasis —In regard to filariasis the discovery of Low and James has been confirmed and amplified by several observers Manson has suggested the possibility of reducing lymphatic varix by leading a lymphatic duct below the stricture into a neighbouring vein

Plague —The prompt suppression of plague in Glasgow has further demonstrated the value of energetic sanitary measures in this disease and the large demand for plague vaccine gives encouraging evidence in favour of Haffkine's prophylaxis

Beri beri —The close clinical similarity of beri beri and chronic arsenical poisoning seems to suggest that many cases attributed to the former disease may possibly be in reality due to arsenic

Work for the future —It seems to me that further researches are at the present moment most urgently required in connexion (1) with tropical fevers , (2) with the flora and fauna of the intestine in tropical bowel complaints , and (3) with the question whether European children in the tropics suffer as frequently from malaria as do the children of natives The practical necessity of taking measures against the uncontrolled propagation of gnats in tropical cities is one which in view of recent discoveries can no longer be set aside by sanitary authorities without dereliction of duty

The profession owes its sincere thanks to all those gentlemen who have done so much during the past year—often without remuneration and at considerable personal risk—for the cause of tropical medical science It also owes its thanks to those British merchants who have generously subscribed large sums of money for the prosecution of many of the researches to which I have referred.

NAVY, ARMY AND AMBULANCE

WEDNESDAY, JULY 31ST

The Presidential Address

Deputy Surgeon General W G Don delivered the following introductory remarks at the opening of the section.

Service Medical Problems

To facilitate procedure during the three days at our disposal we propose to discuss, first naval, secondly, military; and thirdly, civil matters, so far as can be arranged. On naval questions we are promised papers by naval medical officers on most important subjects—namely, the disposal of the wounded in naval actions, and the relative healthfulness of modern warships, to which attention has lately been called. I will not venture to anticipate what may be said on these matters further than to remark that while we probably have data sufficient for arriving at some definite conclusions as to the healthfulness of ironclads, our experience is as yet very limited regarding the disposal of the wounded in modern sea fights. The subject is complicated on account of the many different structural types of our warships, each requiring special contrivances of its own. I may be allowed to express much personal interest in such naval problems, because of lasting early experiences, for it was my fortune to learn something of the interior economy of our wooden walls of 50 years ago, having served for six months as a medical volunteer in H.M.S. *Duke of Wellington*, flagship of the Baltic Fleet of 1855, and taken part in the three days' bombardment at Sweaborg. Such a reminiscence brings the obvious reflection how marvellously and completely have naval life and warfare changed within my own limited recollection. With the military medical problems which may engage our attention I am, after 44 years' consecutive and continuous service in the army, naturally very fairly conversant. I confess that I regard these problems, after the experience of many mutations both in the home and Indian services, as still presenting grave difficulties, and even dangers, unless warily and judiciously handled. Major Dick, R.A.M.C., assistant professor of military surgery, Netley, was to have recounted some aspects of small-bore wounds as inflicted during the war which have come under his direct observation, but we regret his inability to do so. We already know sufficient of such wounds to warrant the anticipation that when the full surgery of the war is made known we shall have some startling revelations, especially in regard to penetration of viscera by small-bore bullets. I lately saw a wounded soldier on sick furlough who while lying down was hit by a Mauser bullet; the missile entered the right chest below the armpit and, passing in a slanting direction, emerged in the region of the left kidney. From its course and the resulting symptoms several of the important viscera could not have escaped penetration; yet months afterwards, when I saw him, the only inconvenience experienced was occasional spasm of the diaphragm on sudden exertion. When we meet with such cases and can recall the terrible visceral wounds inflicted by the expanding Minié bullet of 40 years ago, or even by the still more recent Snider or Martini, the pencil-like missiles of the latter-day magazine rifles seem comparatively almost harmless. Field transport for sick and wounded, on which Captain Ward, R.A.M.C., promises to give his recent war experiences, is a subject of great importance and some difficulty, for it is part of the bigger question of army field transport at large, which cannot, or ought not, to be fixed and fettered by inelastic rules, because it must vary widely according to three factors which may operate in any given campaign. These are: the physical nature of the country in which military operations are conducted; the length of the lines of communication; and the required mobility of the fighting force. It is an open question whether the medical service should not have complete autonomy in its field transport, of whatever kind; but I am not inclined to lay much stress on the point further than that it should be autonomous, subject alone to the express disposition of the general officer in command. For necessity—and specially military necessity—can have no law beyond or over-riding that of preservation of the fighting force; and, consequently, however autonomous in theory the medical or other branches of transport may be, there is always the risk, even the probability, that under the pressure of military exigency (as after Paardeberg), it may be appropriated for the supreme transport of food and ammunition. Intimately bound up with the kind and amount of field medical transport is the question of its use, under new conditions, in affording first aid to the wounded in an action. The enormous widening of the zone of fire from modern weapons makes all active duties connected with stretchers and ambulances increasingly difficult and dangerous. It is now next to impossible with any safety for bearers to keep in touch with an advancing fighting line, while the distances between the combatants may be so great as to render the distinguishing of red crosses and Geneva badges impossible; hence probably the complaints that the ambulances have been deliberately fired on. Not only does the range of fire exceed that of unaided vision, but the use of smokeless powder makes location of a firing line more a matter of the ear than the eye; there is plenty of noise but little to be seen. A wounded cavalry soldier told me he had been six times under fire, but never once saw a living fighting Boer while engaged. In means for affording civil first aid to sick and injured persons in our great urban centres we seem lamentably behind many continental and American cities. We all trust this reproach may before long be removed. It is a question whether motor might not be substituted for horse ambulances for all emergent purposes. Important questions connected with enteric fever will be brought to your notice.

THE ANNUAL MUSEUM.

The allotment of space this year for the annual exhibition of drugs, foods and food products, surgical appliances, and the like, was decidedly generous. Moreover, the Winter Garden itself, in which the exhibit was held, proved a source of attraction, and the lawns outside formed a pleasant retreat and promenade. It was evidently the intention of the organising authorities to make this section of the meeting more attractive and interesting than on previous occasions and in this intention they succeeded. To begin with, the members and friends were invited to an "At Home" and reception in the Winter Garden and grounds on the opening night of the meeting (Monday, July 29th). The spacious lawns were prettily illuminated with fairy lamps and light refreshments were provided under gaily decorated marquees. There was a very considerable response to the invitation and in this way practically the whole of the members and their friends were brought into acquaintance with the fact that an interesting exhibition could be witnessed and that as soon as the social aspect of the gathering had subsided the visitor could more seriously turn his attention to the interesting and attractive array of new medicinal preparations, new methods of administration, new clinical apparatus, new surgical appliances, and even newly designed broughams and motor-cars specially constructed for the use of the general practitioner. The exhibition was an undoubted advance on those of previous years, not excepting even that in London. Indeed, the number of exhibitors exceeded those of all previous occasions by at least 25 per cent. and the interest shown by the visitors was not less than before, while the attendance was proportionately satisfactory. All this was, of course, highly appreciated by the exhibitors themselves and the visitor's interest in the exhibition was maintained. The organising authorities may be heartily congratulated upon thus devoting more attention than usual to this important and interesting section of the annual meeting. The show in the Winter Garden called to mind an exhibition in the Crystal Palace, but of course on a somewhat smaller scale. In the centre of the "garden" was a fountain which proved an important adjunct in a space where many people were gathered together. There can be no doubt that a stream of water through the air freshens and cools it. At the rear of the Winter Garden was a large marquee in which were displayed models of broughams, motor-cars, motor-cycles, and ambulance wagons. For the convenience of visitors a lounge was provided and refreshments could also be obtained in another well-appointed section. The accommodation provided on the present occasion was much more adequate and much more comfortable than in past years. The exhibition is bound to be of a more or less trade description, but we still think that some acceptable relief might be brought into the exhibition by having here and there a few demonstrations of a really scientific kind. As in previous years, the only exhibit that could be claimed to be of this class was the x-ray apparatus. Last year, on the occasion of the exhibition at Ipswich, we pointed out that practically no steps were taken to keep out of the museum a merely curious public to whom in many cases samples of the latest remedy for headache, &c., were freely supplied. We suggested that this indiscriminate distribution of, perhaps, powerful drugs was undesirable, and apparently our suggestion has been acted upon as far as possible, for only those were admitted to the museum who could show cards or who could give evidence that they were in some way or other connected with the medical profession. Members of the medical profession only were allowed in the pathological museum adjoining.

In noticing the more important exhibits this year some classification is convenient and for this purpose we may adopt the following heads —I., Drugs, II, Foods and Food Prod [illegible] Disinfectants, &c ; IV, Sc [illegible] V, Mineral Waters, Be [illegible] VII, Miscellaneous

I —DRUGS

On the whole no striking departure in regard to drugs can be recorded of the exhibition this year There seemed to be a tendency to give more attention to the old style of preparations, and instead of drugs in the many portable forms being shown, extracts, essences, emulsions, tinctures, and elegant fluid preparations were rather the rule. Most of the stalls were arranged with considerable skill and certainly the *tout ensemble* would be much less attractive if drugs, liquid and solid, put up in all sorts and shapes of glass bottles, jars, and trays, coloured and uncoloured, were not exhibited The stall of Messrs Ferris and Co of Bristol was particularly well arranged and displayed evidences of decided energy and skill The various exhibits were most attractively grouped and besides drugs there were a number of "up to date" surgical and medical appliances on view Among the novelties we may mention the saxol petroleum emulsion, a combination of a highly refined petroleum with the hypophosphites; an antiseptic ether soap for cleansing the hands before and after operating and for preparing the skin of patients previously to operation, compound menthol and liquorice pellets, a small urine test case for the pocket, and many other preparations besides those described equally exemplifying pharmaceutical skill. Lastly, we should mention the excellent series of vaccination pads made by this firm, that known as No 20 having a plain absorbent centre with a self-adhesive margin There were many notable examples of modern pharmaceutical preparations on the well arranged stall of Messrs Wyleys, Limited, of Coventry Amongst these should be mentioned the syrup glycerophosphates, a clear and permanent solution of the various glycerophosphates and very palatable, "tropels," or compressed lozenges, made in accordance with B P requirements, ointments in flexible tubes, including [illegible] designed, anti- [illegible] ler, a special [illegible] ; non-alcoholic tinctures and standardised tinctures; and various improved compound preparations Equally effective was the display of Messrs C J Hewlett and Son of 35-42, Charlotte street, London, E C Amongst the new drugs shown here were the fluid extract and tincture of monsonia, which has been used with success in the treatment of dysentery and diarrhœa, isphagul, for the same disorders, and preparations of the cacodylates. The exhibit included some useful sets of clinical tests in urine analysis and a series of original pharmaceutical preparations well known in connexion with this firm. Amongst these were mist senecio co and mist. tussi rub conc, and a liquid ether soap Amongst the novelties on the stall of Messrs Oppenheimer, Son, and Co, Limited, of 179, Queen Victoria street, London, E C, were the suprarenal fluid extract, palatinoids of tinctures prepared from carefully standardised concentrated solutions, traumatol or cresylic acid, a bactericidal agent not less powerful than mercuric chloride, and many ingenious and effective vaporisers To these we should add a new hypodermic case not larger than a cigarette case containing a hypodermic syringe with regulating plunger, two steel needles, a bundle of wires, and 17 tubes of Messrs. Oppenheimer's soluble hypodermics Palatinoids also are now prepared containing the compound glycerophosphates The palatinoids serve to preserve the glycerophosphates from the influences of the atmosphere Messrs Parke, Davis, and Co of 111, Queen Victoria street, London, E C had a stall full of examples of modern pharmaceutical advance Amongst these should be mentioned adrenalin, the active principle of the suprarenal gland, a powerful astringent, hæmostatic, and cardiac and vaso-motor stimulant. The exhibit included nucleinic acid compounds of mercury, silver, iron, and copper, and chloretone, a now well-known local anæsthetic, hypnotic, and antiseptic A very interesting series of synthetics and other fine preparations was presented to view by the Bayer Company, of 20, Booth-street, Manchester Amongst these were aspirin, a substitute for the salicylates, epicarin, a powerful parasiticide, heroin, a morphia derivative which does not cause constipation, while it stimulates expectoration; protargol, the silver proteid preparation now of known value in gonorrhœa, and several somatose preparations The feature of the stall of Messrs Burgoyne, Burbidges and Co, 12 and 16, Coleman street, London, E.C, were some interesting new silver preparations Amongst these were collargolum, described as metallic silver in a new allotropic modification, quite soluble in water It is said to be non irritant and non poisonous, but an effective antiseptic. The citrate and lactate of silver may also be mentioned, the latter being supplied in powder form and in tablets Mr Frank A Rogers of 327, Oxford street, London, W; exhibited a very interesting set of approved forms of medical sprays and atomisers besides various pharmaceutical preparations Amongst the latter was a clear colourless oil, a specially refined petroleum product without taste and odourless, and known as "aquol" The same oil is modified by the addition of benzoin, both are used in a special spraying apparatus designed by Mr Rogers, which has the advantages of simplicity of design, of being easily cleaned, and of producing a uniform spray. Mr E Merck of Darmstadt (16 Jewry-street, London E C) showed a very great number of his well known fine pharmaceutical chemicals, including alkaloids, glucosides, organic and physiological preparations, reagents, and some beautifully pure specimens of modern drugs, chiefly synthetics Amongst the latter may be mentioned cacodylic acid and the cacodylates; bromipin, an organic bromide, iodipin an organic iodide, jequiritol, and many others The materia medica and pharmacology of all these are described in Merck's circular Local pharmacy was well represented in the exhibit of Messrs Thomas Brothers of Bath-road, Cheltenham They showed the interesting combinations of albumin with the halogens—namely, chloralbacid and iodalbacid. The exhibit included an assortment of photographic apparatus and clinical thermometers At the stall of Messrs Arthur and Co of 69, Berners-street, London, W, special emphasis was laid upon the value of bromaurum and hydraurum, the former being a double salt of gold and arsenic, for the treatment of neurasthenia, epilepsy, and rheumatism Some interesting synthetics were shown at the stand of Messrs. Zimmer and Co of Frankfort-on-Maine Amongst these were euquinine, described as a tasteless quinine and possessing the same anti-malarial properties but not causing "cinchonism" or gastric disturbance Again, eupyrine is described as far superior to phenacetin, producing no depression on account of the vanillin contained in its molecule Messrs Corbyn, Stacey, and Co, of 300, High Holborn, London, W C, had an excellent assortment of new pharmaceutical preparations, including the cacodylates, among them being a useful modification for tuberculous patients—namely, the cacodylate of guaiacol The exhibit included also aspirin and chloretone, the comparatively new anæsthetic prepared from chloroform, acetone, and potash These pharmacists have published some very useful notes on new drugs The Abbey Effervescent Salt Company, of 144, Queen Victoria street London, E.C, devoted the space allotted to them entirely to their special preparation, Abbey's effervescent salt We have quite recently dealt with this agreeable saline aperient in our analytical columns What are now well known as the Fairchild products were exhibited by Messrs Fairchild Brothers and Foster, Snow Hill-buildings, London, E C Amongst these products were diazyme, a clear essence containing animal diastase, the active digestive properties of which we have confirmed in our laboratory experiments; other digestive preparations and enzymol, a purified solution of the proteolytic enzyme Mr Peter Möller of 18, High Holborn, London, W C, exhibited a very interesting model of the apparatus in which hydroxyl free cod liver oil is produced As we have previously shown, the excellence of Möller's oil depends upon this particular method of preparation which prevents the formation of objectionable hydroxyls which endow cod liver oil with nauseating properties and a tendency to cause unpleasant eructation

(*To be continued*)

Medical News.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN —At the annual general meeting of this society, held in London on July 26th Dr A E Sansom being in the chair, it was stated that during the past session the membership had increased from 102 to 237 A volume of reports will be issued shortly The following office bearers were elected at the meeting Mr Henry Armstrong (Wellington College), Dr Henry Ashby (Manchester), Dr Fletcher Beach,

Dr. James Carmichael (Edinburgh), Dr. Edmund Cautley, Dr. Wayland Chaffey (Brighton), Dr. Leonard Guthrie, Dr. Robert Hutchison, Dr. Charles Macalister (Liverpool), Dr. John McCaw (Belfast), Dr. Lewis Marshall (Nottingham), Dr. Ernest Sansom, Dr. George Shuttleworth, Dr. George Sutherland, Dr. Frederick Taylor, Dr. James Taylor, Dr. Charles Willey (Sheffield), and Dr. Dawson Williams. Mr. Watson Cheyne, Mr. Walter Edmunds, Mr. Francis Jaffrey, Mr. Robert Jones (Liverpool), Mr. Betham Robinson, and Mr. Alfred H. Tubby were appointed members of the council. Mr. R. Clement Lucas was appointed honorary treasurer and Mr. Sydney Stephenson, Dr. George Carpenter, and Dr. Theodore Fisher (Bristol) were elected honorary secretaries.

DEVON AND EXETER HOSPITAL.—At the quarterly meeting of the supporters of the Devon and Exeter Hospital, held on July 25th, it was reported that the unfavourable balance of £2535 had been reduced, mainly by a legacy, to £872

MEDICAL MAGISTRATE. — Mr. Thomas John Carson, L.F.P.S. and L.M. Glasg., has been placed on the Commission of the Peace for the Borough of Oldham.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Isolation Hospitals.

THE Bill to strengthen the powers of local authorities with regard to the construction and maintenance of isolation hospitals has now received the Royal assent and is therefore part of the law of the land.

Army Medical Service.

A debate on this subject was expected in Committee of Supply on Thursday, July 25th, but so much time was occupied with the discussion of the vote for the salary of the Secretary of State for War, that the Medical Vote had to be postponed.

Beer Bill.

The promoters of the Beer Bill, influenced by the prospect of difficulties in the Grand Committee and the pressure of Government business in the House of Commons, determined to abandon the Bill for the session, and on Friday, July 26th, the measure was formally withdrawn.

The Sale of Intoxicating Liquors to Children.

The Bill to prevent the sale of intoxicating liquors to children is now altered very much in form. The limit of age stands at 14 years instead of 16. Liquors sold or delivered in corked and sealed vessels in quantities not less than one reputed pint for consumption off the premises are excluded from the scope of the Bill altogether, and the sender of the child is made equally punishable with the licence-holder who sells or delivers the liquor to the child. The term "corked" is defined to mean closed with a plug or stopper, whether it is made of cork or wood or glass, or some other material, and "sealed" is defined as secured with any substance without the destruction of which the cork, plug, or stopper cannot be withdrawn.

HOUSE OF COMMONS.

THURSDAY, JULY 25TH.

Dr. Koch and Tuberculosis.

Mr. CAREW asked the President of the Local Government Board whether he was aware of the statement made at the British Congress on Tuberculosis by Professor Koch, and whether in consequence thereof he would cause the recommendation issued long since by the Local Government Board to the inspectors and medical officers of health to refrain from confiscating or destroying the bodies of animals alleged to be affected with localised tuberculosis to be carried out in future.—Mr. LONG replied: I am aware of the statement made by Professor Koch as to the non-identity of human and bovine tuberculosis, but I do not think that this view can at the present time be regarded as having received the general assent of scientific men. The matter is one which will require very careful consideration and I could not promise to take any action which is based on the view referred to.

Medical Provision for Sick and Wounded Officers.

General LAURIE asked the Secretary of State for War whether hospital accommodation was provided for sick and wounded officers returning to this country from the seat of war; if so, whether the accommodation provided had been found sufficient for all cases that required attention; and whether for such officers as were not accommodated in hospital professional attendance was furnished at the public expense, and a pecuniary allowance given to meet the cost of private hospital, provision of nurses, or other necessary outlay.—Mr. BRODRICK replied: At Netley 16 beds are available and 75 officers in all have been treated there. At Herbert Hospital two beds are available, but none have applied to be treated there. More officers might have availed themselves of the accommodation provided in these hospitals. As regards private accommodation it was provided in some cases free of expense owing to the generosity of private organisations. The question of providing for private medical attendance at the public expense is under consideration.

Lead Poisoning Cases.

Mr. COGHILL as[illegible] whether he was aware that, out of 64 cases of [illegible] during June, only eight cases were in the chin[illegible]; and could he state in what trades chiefly the remaining 56 cases occurred; and for what reason the Home Office issued new special rules for the china and earthenware industries rather than for the trades where there were a greater number of cases of lead poisoning.—Mr. RITCHIE replied: The figures quoted by the hon. Member are correct, but it might be added that the eight cases in the china and earthenware trades included two out of the total of four fatal cases for the month. The remaining 56 cases were spread in small numbers over several trades. There is only one trade, the manufacture of white lead, in which the number of cases is greater than in china and earthenware, and for that trade new rules have recently been made. The reasons for proposing the new rules for china and earthenware are fully given in published reports and in letters to the manufacturers

FRIDAY, JULY 26TH.

Typhoid Fever among the Troops.

Mr. BRODRICK, in reply to a question by Sir WALTER FOSTER, said that for the five weeks ended May 31st the admissions from typhoid fever among the troops in South Africa were 2300 and the deaths were 326.

MONDAY, JULY 29TH.

The Case of Dr. Scott Tebb.

Mr. CORRIE GRANT asked the President of the Local Government Board (1) whether he was aware that Dr. Scott Tebb was elected medical officer of health by the Urban District Council of Penge after open competition in response to public advertisement; (2) could he state why the Local Government Board refused to sanction the appointment; (3) whether he required a profession of belief in vaccination from all persons before sanctioning their appointment as medical officer of health; and (4) would he say what duties in securing vaccination were imposed on medical officers of health to urban district councils.—Mr. LONG replied: The case of Dr. Tebb was fully discussed a short time ago by the hon. Member and others on the vote for the Local Government Board, and, as t[illegible] sanction to his appointment was refused on account of [illegible] relation to vaccination. The answer tc[illegible] is in the negative. As regards the last [illegible] is much concerned with vaccination as being the most effectual means of preventing the spread of small-pox, and in the event of an outbreak of that disease in his district it would devolve upon him to do his utmost to promote vaccination and revaccination.

Case of Brass-poisoning.

Dr. FARQUHARSON asked the Home Secretary whether his attention had been called to an inquest recently held by the Birmingham city coroner on a young man named Martin Brannon, who died from pneumonia and tubercle, certified by Dr. Moir, medical officer to the Ladywood Dispensary, to be due t[illegible] whether, in view of the statement that a large [illegible] women, and girls employed in the 400 b[illegible] am were suffering, or had suffered, from the well-known symptoms of this disease, and that the coroner stated that this was a case for inquiry, he would cause inquiry to be made.—Mr. RITCHIE replied: My attention has been called to the case by the coroner. The question of the danger to health from dust in brass-polishing and in the polishing of other metals has for some time been engaging the attention of the factory staff and especially of the medical inspector of factories. I will make further inquiry into the matter and consider what steps ought to be taken.

Civil Surgeons with the Forces.

Mr. MACNEILL asked the Secretary of State for War whether the pay of civil surgeons who had served for three years with the Imperial forces would be rendered at the end of that period on a similar scale to the pay of members of the Royal Army Medical Corps.—Mr. BRODRICK replied that the matter was under consideration.

Research on the Subject of Cancer.

Mr. WEIR asked the First Lord of the Treasury whether he was aware that at a recent gathering of the foreign delegates to the Tuberculosis Congress reference was made to cancer as the one other disease which had up till now baffled the scientific and medical men of the world; and whether, in view of the increase of this disease, he would consider the advisability of the appointment of a commission or committee to inquire what steps could be taken for aiding research into the cause, cure, and prevention of this disease.—Mr. BALFOUR replied: I cannot believe that a commission would be the proper machinery for the carrying out of such a delicate and difficult matter of research as that referred to in the question of the hon. Member. The prevalence and the increase of this disease are occupying every medical mind over the whole of the civilised world and I do not think that the appointment of a commission would either aid or stimulate inquiry.—Mr. WEIR then asked the right hon. gentleman whether the Government would consider the advisability of appropriating a sum of money in aid of this research.—Mr. BALFOUR replied: It is necessary that some definite proposal should come to us indicating that the grant of public money might have satisfactory results before we could assent to any such course.

The Royal Commission on Arsenical Poisoning.

SIR CUTHBERT QUILTER asked the President of the Local Government Board, now that the Beer Bill had been withdrawn, what measures the Government proposed to adopt to prevent the introduction of deleterious or poisonous substances into beer, more particularly as the Royal Commissi[illegible] in their report just issued expre[illegible] f the Beer Mate[illegible] neither the Inlar[illegible] s appeared to possess powers or machinery adequate for the [illegible] otection of the public.—Sir MICHAEL HICKS BEACH replied to the question, saying: I cannot accept my hon. friend's premisses. The Beer Bill proposed no machinery for preventing the introduction of deleterious or poisonous substances into beer, and as the presence of arsenic in beer was not suggested as a subject particularly deserving the consideration of the Beer Materials Committee, the report of the Royal Commission which [illegible] adopt [illegible] that [illegible] will [illegible] require [illegible] public

The Government and Tuberculosis.

Mr. FIELD asked the President of the Local Government Board (1) whether he was aware of the [illegible] Tuberculosis Congress asking for [illegible] pointing such a commission and [illegible] with the meat and milk trades, [illegible] and scientists.—Mr. LONG said: The [illegible] the question is in the affirmative. As [illegible] already have the matter under my [illegible]

The Army Medical Service.

Captain NORTON asked the Secretary of State for War if he could [illegible] Army Medical Department on [illegible] June 1st last have not been [illegible] various measures for the re[illegible]nt are not yet completed.—[illegible] know is why the promotions of these officers have been delayed.—Mr. BRODRICK: The reorganisation might affect those promotions.

Plumbism in the Printing Trade.

Mr. TULLY asked the Home Secretary whether, seeing that the cases [illegible] last year were one in every 3000 [illegible] would take any steps to exempt [illegible]rades from the operations of the [illegible] Amending and Consolidating the [illegible]hat since this matter was under [illegible]n Trade he had come to the conclusion that some alteration of the clause in question was necessary, and he was now considering the precise words of the amendment he would propose.

Musselburgh Infectious Diseases Hospital.

The LORD ADVOCATE, in reply to a question on the above subject, [illegible] powers to insist on the erection of a proper hospital and when also sanitation was much less advanced than it now is as regards isolation of infectious dis[illegible] was probably the best that cou[illegible] erected for hospital purposes; it [illegible] all and indeed greatly superior [illegible]

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.*

ALLEN, WILLIAM T. D., M.B., B.Ch. R.U.I., has been appointed Medical Officer for the Fourth District of the Parish of Liverpool, vice S. Caldwell, M.R.C.S. Eng., resigned.

BELFRAGE, SYDNEY H., M.B., L.R.C.P. Lond., M.R.C.S. Eng., has been appointed Assistant Anæsthetist to the Dental Hospital of London.

BERRYMAN, EDMUND N., L.R.C.P. Lond., M.R.C.S. Eng., has been appointed District and Workhouse Medical Officer of the Llandovery Union.

BUCK, ARTHUR H., F.R.C.S. Edin., M.R.C.S. Eng., L.R.C.P. Lond., has been appointed Honorary Surgeon to the Brighton, Hove, and Sussex Throat and Ear Hospital.

BURGESS, ARTHUR H., F.R.C.S. Eng., M.B., Ch.B., M.Sc. Vict., has been [illegible] the Man[illegible] Certifying [illegible] Dundee, [illegible] District of Dundee.

HAWORTH, STEPHEN R., M.D., B.Ch., R.U.I., has been appointed District Surgeon of Boshof[illegible] Cape Colony.

HEWLETT, RICHARD TANNER, M.D., M.R.C.P. Lond., has been appointed Professor of General Pathology and Bacteriology in King's College, London.

HIGGENS, PYEFINCH, M.B., B.Ch. Oxon., M.R.C.P. Lond., has been [illegible] al Infirmary. [illegible] ted Medical Officer [illegible] (Devon) Board of Guardians.

HUTCHINSON, ARTHUR J., M.B., C.M. Glasg., has been appointed Honorary Assistant Surgeon to the Brighton, Hove, and Sussex Throat and Ear Hospital.

JACOBS, H. R., M.R.C.S. Eng., has been appointed District Medical Officer of the Brackley Union.

JOHNSON, ALICE N. VOWE, M.D. Brux., L.R.C.P., L.R.C.S. Edin., has been appointed Junior Assistant Medical Officer to the Carmarthen Asylum.

MAR[illegible]

PAR[illegible] Medical, [illegible] been ap[illegible] appointed Resident House Surgeon of the Carlisle Dispensary.

THOMSON, STCLAIR, M.D., M.R.C.P. Lond., F.R.C.S. Eng., has been elected Assistant Physician for Diseases of the Throat in King's College Hospital.

TREVES, EDWARD, M.R.C.S. Eng., L.R.C.P., has been appointed Honorary Consulting Surgeon to the Brighton, Hove, and Sussex Throat and Ear Hospital.

WATSON, JAMES, L.R.C.P., L.R.C.S. Edin., has been appointed District Medical Officer of the Alnwick Union.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BIRMINGHAM AND MIDLAND SKIN AND URINARY HOSPITAL, John Bright-street.—Surgical Assistant for six months, [illegible]

BIR[illegible]

BIR[illegible]

BRE[illegible]

BRI[illegible] with board and residence.

BRIGHTON, HOVE, AND SUSSEX THROAT AND EAR HOSPITAL, Church [illegible] House Surgeon.

[illegible] House Surgeon.

[illegible] CHEST, Victoria [illegible] Salary at rate [illegible]ng.

[illegible]NARY.—Junior [illegible]m, with board, [illegible]

[illegible] Resident Medical [illegible] board and apartments.

DENBIGHSHIRE INFIRMARY, Denbigh.—House Surgeon. Salary £100, with board, residence, and washing.

[illegible]nster.—Third Assistant Medical Officer [illegible] per annum, and increasing at the rate [illegible] with board, residence, &c.

[illegible]ton, Derbyshire.—Assistant House [illegible] annum, with furnished apartments, [illegible]

[illegible]wich.—Resident Junior House Surgeon. [illegible] with board, lodging, washing, and [illegible]

EAST SUFFOLK AND IPSWICH HOSPITAL.—Second House Surgeon, unmarried. Salary £80 per annum, with board, lodging, and washing.

ESS[illegible] House Surgeon

GUI[illegible] Surgeon for six months, [illegible] board, and washing.

HUL[illegible] Salary £60 per annum, with board and lodging.

KENT AND CANTERBURY HOSPITAL.—Assistant House Surgeon, unmarried. Salary £50 a year, with board and lodging.

LAWN HOSPITAL FOR INSANE, Lincoln.—Assistant Medical Officer. Salary £100.

LEWES DISPENSARY AND INFIRMARY AND VICTORIA HOSPITAL.—Resident Medical Officer. Salary £100 per annum, furnished apartments, board, coal, gas and attendance.

[illegible] six months, [illegible] period of six [illegible] £100 per [illegible] Surgeon, un[illegible] every year, [illegible] [illegible] Salary £80 per annum, with board, lodging, and washing.

ROYAL CORNWALL INFIRMARY.—House Surgeon, unmarried. Salary £100, increasing by £10 a year, with board (excluding stimulants) and apartments.

ROYAL INFIRMARY, Sheffield.—Senior Assistant House Surgeon. Salary £80 per annum, with board, lodging, and washing. Also Junior Assistant House Surgeon. Salary £70 per annum, with board, lodging, and washing.

ROYAL LANCASTER INFIRMARY.—Assistant House Surgeon, single. Salary £60 a year, with residence, board, attendance, and washing.

ROYAL SOUTH HANTS AND SOUTHAMPTON HOSPITAL.—Junior House Surgeon for six months. Salary at rate of £50 per annum, with rooms, board, and washing. Also Dispenser. Salary £60 per annum, with board, rooms, and washing.

RUBERY HILL ASYLUM, Barnt Green, Worcestershire.—Junior Assistant Medical Officer. Salary £130 per annum, with board, furnished apartments, &c.

SALOP INFIRMARY, Shrewsbury.—House Surgeon. Salary £100 per annum, with board, washing, and residence.

SOMERSET AND BATH LUNATIC ASYLUM, Wells, Somerset.—Medical Superintendent. Salary £600 per annum, with furnished house and allowances.

TAUNTON AND SOMERSET HOSPITAL, Taunton.—Assistant House Surgeon. Salary at the rate of £60 per annum, with board, lodging, and laundry.

TOTTENHAM HOSPITAL.—Senior Resident Medical Officer. Salary £90 per annum, with board, residence, and laundry.

VICTORIA HOSPITAL, Folkestone.—House Surgeon. Salary £100 per annum, with board, residence, and laundry.

WANDSWORTH AND CLAPHAM UNION INFIRMARY, St. John's-hill, S.W.—Junior Assistant Medical Officer. Board, lodging, and washing provided. Salary £70 per annum, payable quarterly.

WEST AFRICA.—Three Medical Officers. Salaries offered £40 per month, plus subsistence allowance, first class passages, and outfit allowance.

WEST HERTS INFIRMARY, Hemel Hampstead.—House Surgeon, single. Salary £100 per annum, with furnished rooms, board, fire, lights, washing, and attendance.

WHITEHAVEN AND WEST CUMBERLAND INFIRMARY.—House Surgeon. Salary £120 per year, and £30 per year for Dispensing, with furnished apartments and attendance.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—Assistant House Surgeon. Honorarium at the rate of £75 per annum will be given. Board, lodging, and washing provided. Also Assistant House Physician. Honorarium at the rate of £75 per annum will be given. Board, lodging, and washing provided.

WOLVERHAMPTON EYE INFIRMARY.—House Surgeon. Terms, £70 per annum, rooms, board, and washing.

Births, Marriages, and Deaths.

BIRTHS.

BEATTY.—On July 29th, at Melrose, Clacton-on-Sea, the wife of T. Carlyle Beatty, M.D., of a daughter.

CALEY.—On July 29th, at Colville House, Ealing, the wife of Guthrie Neville Caley, M.D., of a son.

EDWARDS.—On July 29th, at Peckham-road, the wife of Francis H. Edwards, M.D., M.R.C.P., of a son.

GILBERTSON.—On July 28th, at Hitchin, the wife of James Henry Gilbertson, M.R.C.S., L.R.C.P. Lond., of a son.

LANGFORD.—On July 25th, at Weston-park, Crouch-end, N., the wife of C. Harris Langford, M.B. Lond., of a daughter.

MANSELL-WOODHOUSE.—On July 21st, at Beaumont-street, W., the wife of Walter Mansell-Woodhouse, M.R.C.S. Eng., L.R.C.P. Lond., Wantage, Berks, of a son.

WILLIAMS-FREEMAN.—On July 23rd, at Weyhill, Andover, the wife of John P. Williams-Freeman, M.D., of a daughter.

MARRIAGES.

EVANS—BEENHAM.—On July 23rd, at St. John the Divine's, Richmond, by the Rev. A. W. Goodwin, David Robert Powell Evans, L.R.C.P. Lond., M.R.C.S. Eng., L.S.A., to Jessie, daughter of Charles Beenham.

HILL—FREND.—On July 24th, at St. Pancras Church, by the Rev. R. J. Golding-Bird, D.D., Joseph Shuter Hill, L.R.C.P., M.R.C.S., to Rebecca Billingsley, widow of A. B. Frend and only child of the late John Indermaur.

HORSFALL—CAMPBELL.—On July 24th, at Holy Trinity, Melrose, by the Rev. W. Horsfall, Charles Edward Horsfall, M.B., Bedale, Yorkshire, to Lilias Marianne, daughter of Robert Hume Campbell, of Glendaruel, Argyllshire.

LAWTON—GILMOUR.—On July 25th, at St. Michael's Church, Birkenhead, by the Rev. A. Hamilton King, William Lawton, M.B., to Florence Purdon, only child of the late James Gilmour, F.C.S.

STABB—FROUDE.—On the 30th July, at Marylebone parish church, by the Rev. Cecil Wood, Ewen Carthew Stabb, F.R.C.S., of 57, Queen Anne-street, W., eldest son of William Henry Stabb, of Ilfracombe, to Emma Langworthy, daughter of the late James Henry Froude, of Newent, Glos.

DEATHS.

BLACK.—On July 23rd, at Tête du Lion, Valtournanche, Italy (the result of an accident), Robert Black, M.D., of Pavilion-parade, Brighton.

HORSFALL.—On July 23rd, at Newland House, Leamington, Francis Horsfall, M.R.C.S. Eng., L.R.C.P. Edin., aged 80 years.

SCOWCROFT.—On July 10th, 1901, John Edwin Scowcroft, M.D., Mayor of Bolton, Surgeon-Captain 2nd V.B. L.N.L. Regiment, at his residence, Oakleigh, Great Lever, Bolton, aged 56 years.

WILLIAMS.—On July 26th, at Ramsgate, John Worthy Williams L.R.C.P. Lond., aged 44 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE UNQUALIFIED PRACTITIONER AGAIN.

MR. P. P. MAITLAND, the coroner for the West Riding District of Yorkshire, held an inquest at the Clothiers' Arms Hotel, Batley Carr, recently, on the body of the infant son of Theophilus Whitehead, miner, of Common Side, Hanging Heaton, Batley. Evidence was given by several witnesses.—Coroner (to the father): Was it your idea that Howarth should attend?—Well, we went for the nearest.—Did you know that he was not a properly qualified man? —No, he said that if the child died he could give a certificate.—Why did you ask him if he could give a certificate?—Because he had had some bother before about giving one.—As there had been a difficulty before why did you go to him?—Well, he said he had got over it and could give a certificate now. He said he had also some letters from the Registrar-General on the subject.—The coroner pointed out to witness that the certificate given by Howarth in one place said death was due to asphyxia and in another to premature birth.—Witness: Well, they told me he was a qualified man.—Coroner: I only wish to point out again that asphyxia means death from suffocation and that is totally wrong. It is a pity that he is employed by unintelligent people. Such men as Howarth who are unqualified and uneducated should not, in his (the coroner's) idea, be allowed to practise. He had had a similar trouble with the same man before.—Mr. Charles D. Garrett of West Town, Dewsbury, had made a post-mortem examination of the body and from that said he found that the cause of death was heart failure due to premature birth and that the certificate given by Howarth was totally wrong.—Mrs. Burnley, a neighbour, said that she took the certificate to the registrar (Mr. S. Harrison), but he declined to accept it on the grounds that Howarth was not a qualified practitioner, and he therefore reported the matter to Mr. Maitland. It also appeared from the evidence that a few weeks before the deceased's mother fell upon her face and chest. In the end the jury agreed to a verdict of "Heart failure due to premature birth, probably caused by a fall." Mr. Maitland informed the jury that he would again report the matter to the Registrar-General in London, and he also thought that something ought to be done by the "Medical Association."

"A SAFETY WINDOW-CLEANING APPARATUS."

To the Editors of THE LANCET.

SIRS,—In reference to the article on this subject which appeared in THE LANCET of July 27th, p. 214, I think it cannot be generally known that a reversible window sash has been in the market some little time. It is made by Mr. Linskill, builder, Harrogate. I had one introduced into my house last year and it is perfectly satisfactory. The glass can be cleaned thoroughly from the inside and quite easily. I have asked Mr. Linskill to forward you the descriptive papers on the subject.

I am, Sirs yours faithfully,
Kidderminster, July 29th, 1901. S. STRETTON, M.R.C S Eng

SEA AIR AND ECZEMA.

To the Editors of THE LANCET.

SIRS,—I should be much obliged if some of your correspondents would give me their opinion as to whether sea air is really so hurtful to eczema and some skin affections as most authorities imagine. I have a patient who is about to retire from business and thinks of taking up his residence at Bournemouth; he suffers slightly from eczema.

I am, Sirs, yours faithfully,
P. P.
July 29th, 1901.

LOCUM-TENENTS.

To the Editors of THE LANCET.

SIRS,—Referring to the letter by "M.D. Brux." in THE LANCET of July 27th, p. 258, in which he gives an undoubtedly useful hint to medical men, may I be allowed to do the same by giving several? I would, as a principal and locum-tenent myself, urge on practitioners that it is impossible to obtain good men at low fees. A locum-tenent should be treated as such, not as a temporary assistant. Consequently, principals should see that their agents procure for them only men of some years' experience, for I maintain that a newly qualified man is in no way fitted to act as a "locum-tenent" or one "holding place." A locum-tenent should not only have self-confidence, but should be a man of experience in general practice, and such a man is not willing, nor is it fair to expect it, to take charge of a practice at an assistant's wage. I would say to principals, Do not boast of the good qualities of former locum-tenents and do not talk of the failures of the rest. Do not expect a practice to increase whilst under a locum-tenent's charge and unless negligence can be proved do not blame him. Pay a fair price for a good article and see that it is supplied. As for a locum-tenent, under present conditions, not attending to agents' wires, what about the principal who is taken suddenly ill? Has he to wait to advertise or answer advertisements? In the same issue of THE LANCET (p. 229) is a good letter by "G. P." (headed "The Times are Troublous"), in which he says he believes that although locum-tenents and assistants are scarce the profession was never more overcrowded. My experience of 17 years confirms his statement. But there is a remedy, partial, it is true, but still a help. Never was the locum-tenent more of a necessary and less of a luxury. Why, then, should not men of, say three years' experience and upwards, form a coöperative Locum-Tenents and Assistancy Association? We should then get good, experienced men and the locum-tenent would feel that he was a recognised member, not a parasite, of the profession. A house could be hired in London, so that in the intervals between engagements locum-tenents could be lodged, &c., at a fair price and always ready to go anywhere. In fact, the nursing homes could be taken as a model. Further, I will say that if this were done there are many able men who would rather live as I suggest than starve in their so-called practices, and who have started their so-called practices rather than put up with the petty tyrannies of some—and I am glad to be able to say it, a few—principals. I trust this letter may bear the fruit I desire for it, and I also trust that principals as well as locum-tenents will support the idea.

I am, Sirs, yours faithfully,

July 27th, 1901. L. T.

THE LATE MR. R. B. ANDERSON, F.R.C.S.ENG.

THE committee formed to appeal for aid on behalf of the widow and two sons of Mr. Anderson (see THE LANCET of July 13th, p. 103) beg gratefully to announce the following list of subscriptions to July 28th, amounting in all to £52 10s.

	£	s.	d.
The Earl of Stamford (chairman)	10	0	0
Mr. Timothy Holmes (honorary treasurer)	5	0	0
Mr. H. E. Juler	2	2	0
Dr. Higham Hill	1	1	0
Dr. Lorimer Hart ...	1	1	0
Dr. Alfred Cox	1	1	0
Dr. Wheeler O'Bryen ...	0	10	6
Dr. Milner Browne ...	0	10	6
Mr. Walter Monnington (honorary secretary)...	1	1	0
Lord Lister	10	0	0
Dr. Herbert Owen ...	1	1	0
Dr Duka	1	1	0
Dr. W. Domett Stone ...	1	1	0
Dr. John Brown	0	10	0
A Friend	1	0	0
Sir Thomas Smith	5	0	0
Sir R. M. Craven	1	1	0
Mr. D. E. Llewellyn ...	1	1	0
Dr. T. Granville Hockridge	1	1	0
Dr. C. Crawford...	1	1	0
Mr. J. H. Waddington ...	0	10	6
Mr. W. Smith	0	10	6
Mr. C. Coates	2	2	0
Dr. G. F. Blandford... ...	3	3	0

Mr. Walter Monnington, 7, Fig Tree-court, Temple, E.C., is honorary secretary. Donations for "The late R. B. Anderson Fund" should be sent and made payable to the Manager, Union Bank of London, Chancery-lane, London.

◆

J. P. S.—We do not know the man, but the style of the letter would seem to show that he is one of the touting money-lenders against whom recent legislation was directed. The annoyance to which our correspondent is being subjected is due to his name having got upon the list of one of these persons. They act in combination and exchange lists.

P. V. T. (Longton) is thanked for his letter. There is much to be said for his argument, but the way in which he discusses the matter will not tend to bring about the reform he desires.

Colne.—We cannot answer definitely as sufficient information is not before us. Will our correspondent send us full details of the office which he has filled.

J. C.—There is, we regret to say, no institution of the kind.

Medical Diary for the ensuing Week.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE *Index to Vol. I. of* 1901, which was completed with the issue of June 29th, and the Title-page to the Volume, were given in THE LANCET of July 6th.

VOLUMES AND CASES

VOLUMES for the first half of the year 1901 are now ready. Bound in cloth, gilt lettered, price 18s., carriage extra.

Cases for binding the half-year's numbers are now ready. Cloth, gilt lettered, price 2s., by post 2s. 3d.

To be obtained on application to the Manager, accompanied by remittance.

A Clinical Lecture
ON
MITRAL DISEASE.

Delivered in the Glasgow Royal Infirmary,

By JOHN LINDSAY STEVEN, M.D. Glasg.,
PHYSICIAN TO THE GLASGOW ROYAL INFIRMARY; LECTURER AND EXAMINER IN THE PRACTICE OF MEDICINE, QUEEN MARGARET COLLEGE, UNIVERSITY OF GLASGOW.

Gentlemen,—In the wards at present there are under treatment no less than 10 cases of disease of the mitral valve, and I propose this morning to make them the subject of a clinical lecture upon this affection. Of the 10 cases, nine are in the female ward; and six of them are very definitely associated with acute rheumatism as a causal factor. In the first place I shall read to you short summaries of the clinical histories, and in the second I shall direct your attention to the signs and symptoms of mitral disease which are illustrated by them.[1]

Case 1.—A married woman, aged 24 years, was admitted on Oct. 13th, 1899, suffering from acute rheumatism of three weeks' duration, the present being the second attack. The first attack occurred three and a half years previously and lasted with remissions for several months. There is in this case a very decided family tendency to rheumatic fever. The father and a brother of the patient have had acute rheumatism, and another brother died from chorea and mitral endocarditis in Ward 12 of this infirmary. On admission the patient had moderate pyrexia and the left knee, the right shoulder, and the left breast were the seat of pain and swelling. The pulse has ranged between 80 and 90 per minute and has been regular in force and rhythm and of good tension. There is a soft V.S. murmur at the apex without evidence of cardiac enlargement.

Case 2.—The patient, aged 37 years, married, was admitted on Oct. 23rd, 1899, suffering from mitral regurgitation, accompanied by dull præcordial pain, palpitation, and occasional faintness of nine weeks' duration. The present illness originated after her last confinement, nine weeks ago, when she began to suffer from shortness of breath, cough, and expectoration of pus and blood. She has not been much out of bed since the confinement, which was very laborious. She has been married for five years and has had three children. She suffered from rheumatic fever 15 years ago and was ill for three months. The apex beat is diffused and is situated in the fifth interspace, four and a half inches to the left of the middle line. There is a loud V.S murmur at the apex and the second sound is reduplicated at the base. In the third left interspace and in the tricuspid area a V.D. murmur is heard as well as the V.S. With the exception of slight bronchial catarrh the lungs are normal. The pulse is small, easily compressed, and averages from 65 to 70 per minute.

Case 3.—The patient, a married woman, aged 27 years, was admitted on Sept. 19th, 1899, suffering from mitral regurgitation of rheumatic origin. The illness is of five months' duration and has been characterised chiefly by increasing dyspnœa and œdema of the lower limbs. Her first confinement took place about one month after the onset of the illness, and although the labour was easy it gave no relief to the shortness of breath and the cough from which she also suffers. She had an attack of acute rheumatism 15 years ago and was six weeks ill. The family history is negative. The pulse averages between 85 and 90, but was much more rapid at the time of admission. It is somewhat irregular in force and rhythm. The apex beat is situated in the fifth interspace, about five inches to the left of the middle line, and the cardiac area is enlarged both to the right and the left. A musical V.S murmur is heard over the apex beat and in the fourth left interspace V.S. and V.D. murmurs are audible These murmurs are not heard in the aortic area and very faintly in the tricuspid area. The second sound is accentuated in the pulmonic area.

Case 4.—A girl, aged 12 years, was admitted on Oct. 19th, 1899, suffering from mitral regurgitation and obstruction of at least 13 or 14 months' duration. She suffered from chorea between the ages of five and seven years. She was admitted to the infirmary on Oct. 14th, 1898, suffering from great breathlessness of two or three weeks' duration and with signs of well-marked mitral regurgitation. She was dismissed after six weeks somewhat improved. She had never had acute rheumatism until the present illness and she was admitted in the course of a characteristic attack of rheumatic fever, which, however, subsided soon after admission and since Oct. 23rd there has been no pain in the joints. A sister died from chorea at the age of 14 years. The pulse at first was very rapid, numbering 120 per minute, but was regular in force and rhythm, and now it varies between 90 and 95. The apex beat is situated in the sixth interspace four inches to the left of the middle line. There were loud V.S. and V.D. murmurs at the apex. The V.D. murmur is strictly confined to the apex region. The second pulmonic sound is markedly accentuated. In the aortic area there is great muffling of the cardiac sounds and the V.S murmur is practically inaudible. Since the subsidence of the rheumatism there has been no urgent cardiac symptom. It is worthy of note that on Oct. 14th, 1899, it was observed that a short A.S. murmur preceded the apex systolic murmur.

Case 5.—The patient, a girl, aged 11 years, was re-admitted on Oct. 16th, 1899, suffering from a second attack of chorea, having been dismissed, after recovery from her first attack, on July 28th, 1899. Her pulse numbers 80 per minute and is small, irregular, and easily compressible. During her first residence the heart was normal, but now there is a soft systolic murmur to be heard at the apex. There is no other sign of cardiac involvement.

Case 6.—A female child, aged nine years, was admitted on Oct. 18th, 1899, suffering from shortness of breath and general weakness of about a month's duration. She also suffered from slight pains in the joints. Her pulse is small and easily compressed. At first it varied between 90 and 100, now it ranges between 70 and 80 A very pronounced V.S. murmur is audible over the apex beat, with a suggestion of an A.S. element. There is great accentuation of the second sound both at the apex and the base.

Case 7.—The patient, a man, aged 30 years, was admitted on Oct. 24th, 1899, suffering from mitral regurgitation with well-marked hypertrophy and dilatation of the left ventricle. He was also the subject of well-marked paresis affecting the whole right side and of distinct motor aphasia of an exceedingly pure and uncomplicated kind. No sensory aphasia could be made out.
developed suddenly while he

in very good health. No history of rheumatic fever could be obtained, though he admitted that he suffered occasionally from rheumatic pains. There is nothing in the history to indicate the duration of the cardiac lesion. The apex beat is situated in the fifth intercostal space four and a half inches to the left of the middle line. On placing the hand over the apex beat a slight diastolic thrill can occasionally be felt, and on auscultation a loud systolic murmur is heard, well conducted into the axilla.

Case 8.—The patient, a married woman, aged 53 years, was admitted on Oct.
dilatation, with a soft,
The symptoms were of
and consisted of pain in the præcordium, palpitation, orthopnea, and œdema of the lower limbs. No rheumatic history of any kind could be obtained. The temperature is normal, the face is livid, and the capillaries of the cheeks are injected. The pulse is exceedingly irregular both in force and in rhythm and numbers 110 The apex beat is situated in the fifth interspace, four inches to the left of the middle line, and over it a soft V.S. murmur is heard Comparative dulness is made out at the right base behind, where also numerous fine moist râles are heard.

Case 9.—An unmarried woman, aged 21 years, was admitted on Oct. 27th, 1899, suffering from mitral regurgitation with considerable dilatation of the left ventricle The symptoms were of two years' duration and consisted mainly of cough, shortness of breath, palpitation, and occasional hoarseness This is the fourth illness characterised by similar symptoms since October, 1893 She has suffered from scarlet fever and measles in childhood. She never had rheumatic fever, but she has frequently had severe growing pains. The mitral physiognomy is well marked and there is great œdema of the lower limbs. The pulse, numbering about 80, is very irregular in force and in rhythm. The apex beat is situated in the fifth interspace four and a quarter inches to the left of the middle line. A loud V.S. murmur is heard at the apex and a distinct systolic thrill can be felt.

---

[1] As the [illegible]
"diastolic."

CASE 10.—A girl, aged 12 years, was admitted for the second time on Nov. 7th, 1899. Her first admission was on August 2nd, 1899, and she was dismissed somewhat improved on Oct. 24th. Her first admission was on account of well-marked symptoms of mitral stenosis of about two years' duration in all. Six months before her admission she had frequent attacks of hæmoptysis. The apex beat was situated in the fifth interspace two and three-quarter inches to the left of the middle line. A distinct presystolic thrill could be felt and a loud A.S. murmur, strictly limited to the region of the apex beat, was present. Her present admission is on account of the sudden occurrence of well-marked paralysis of the left side of the face and body. No history of rheumatic fever or of chorea could be obtained. The pulse at present averages about 90 in the minute and is regular in force and rhythm.

All the cases thus briefly summarised have been already brought under your notice in detail in the course of our daily ward visits, when the clinical histories and the physical signs have been minutely investigated and demonstrated. My object at present is to indicate to you in general terms the clinical phenomena of mitral disease which this group of 10 fairly characteristic cases serves to illustrate. In doing this I shall not follow any systematic plan, but shall take up a few of the chief points which are suggested by the clinical summaries which I have just submitted for your consideration.

THE MURMURS OF MITRAL DISEASE.

In all of these 10 cases, with perhaps one exception (Case 8), there is, I believe, definite structural deformity of the mitral curtains and therefore they are of value as enabling us to formulate some idea of the kind of murmurs which may be associated with actual lesion of the mitral valve. The murmur present in eight out of the 10 cases is an apex systolic (V.S.) murmur conveyed towards the axilla. Now it is to be remembered that this murmur need not indicate structural disease of the mitral curtains at all. This murmur may be present in cases where the curtains of the mitral valve are structurally intact. All that it necessarily indicates is that the curtains are not preventing the regurgitation of blood from the left ventricle into the left auricle and this may take place without structural change of the curtains themselves. There is only one murmur which invariably and unmistakeably indicates actual structural change in the mitral curtains and that is the presystolic (A.S.) murmur heard at the apex and limited to this region. As Balfour remarks in his classical lectures, "there is a murmur so invariably associated with disease of the mitral valve that, when once heard, it may be accepted as a positive proof of a permanent deformity of that valve, and that even although the murmur itself may cease to be heard, as not infrequently happens." In two of the above cases only (Case 6 and Case 10) is this positive auscultatory sign of disease of the mitral curtains present. It is a direct murmur and indicates stenosis of the mitral valve, causing obstruction to the passage of blood from the left auricle to the ventricle. Sometimes, however, another murmur is found which may also be regarded as affording fairly positive evidence of actual disease of the mitral curtains, and that is a murmur occupying the long pause, diastolic (V.D.) in rhythm and limited to the apex region in the third left intercostal space. Sometimes the murmur is definitely diastolic in character; sometimes it is heard as an indefinite blow in the long silence. Such diastolic murmurs may probably be regarded as modified or prolonged A.S. murmurs, produced by essentially the same mechanism, and therefore what I have just said of them does not invalidate my previous statement as to the positive signification of the latter murmurs. Both murmurs are direct murmurs. Mitral diastolic murmurs were heard in Case 2 and in Case 4, and in both they were associated with an apex systolic murmur. As regards four only of the ten cases, then, can it be said that we have positive auscultatory evidence of actual lesion of the mitral curtains. As regards the remaining six, however, in which we have only to deal with an apex systolic murmur, there are, I think, five in which we are pretty certain to have structural disease of the mitral curtains, the probable exception being Case 8. As I have said, an apex systolic murmur indicates merely regurgitation from the left ventri- into the auricle, and as this was the only murmur p sent in these five cases it is clear that structural char in the mitral curtains cannot be inferred from its preser above. This is precisely the point which I desire to pr home upon you. Where, in a case of mitral regurgitati you have on auscultation merely a V.S. murmur at the ap you are dependent upon other phenomena to enable you arrive at a diagnosis of pathological alteration of the mit cusps. Chief among these aids to diagnostic precision are history of acute rheumatism or chorea and the occurrence embolism. We find this additional evidence in the five cas which were characterised by the presence of an apex systo murmur alone. In Cases 1 and 2 very clear rheuma history could be made out, and in Case 9 there was a cle account of severe growing pains and of scarlet fever, t latter being capable occasionally of giving rise to end carditis. In Case 5 there occurred two attacks of chore after the second of which the heart became involved; and Case 7 we had to deal with a very definite embolic hem plegia. These are the circumstances, then, which lead me say that in these five cases characterised only by a V. murmur we have to deal with something more than a me regurgitation. In Case 10 we have the interesting combin tion of the positive auscultatory sign and the corroborati embolic phenomenon existing together. In only one ca (Case 8) of the series the apex murmur does not indica actual structural change of the valvular curtains, but mere regurgitation through the orifice. In this case I think is pretty clear that the cause of the incompetence primarily myocardial and not valvular. There is n evidence of endocarditis and the age of the patie is that at which myocardial degeneration is common. Th regurgitation is due to dilatation of the left ventricle an consequent insufficiency of the curtains, hence the ape systolic murmur. The causes and varieties of the murmur of mitral disease are thus well illustrated by the presen series of cases.

THE AGE AT WHICH MITRAL DISEASE OCCURS.

The group of cases also gives us some information on thi point. The youngest patient is nine years of age and th oldest is 53 years of age. Seven of these are under the ag of 30 years. The lesson taught is that structural lesions o the mitral curtains are more likely to originate in childhood and youth than after the middle period of life, and that mitral incompetence due to myocardial degeneration—e.g., Case 8—is essentially an affection of advancing years. It is well to bear this distinction in mind, as it has an important bearing upon the management and treatment of mitral disease. Acute rheumatism with its resulting endocarditis is perhaps the most common cause of disease of the cardiac valvular curtains. Acute rheumatism is essentially a disease of childhood and early manhood. It is also to be remembered that a certain proportion of cases of mitral stenosis in women are perhaps congenital in origin. Hence arises the preponderance of mitral disease due to structural changes in the valvular curtains in the earlier periods of life. While it is probably true that in the later decades of life mitral disease is more frequently primarily associated with organic affections of the myocardium than of the valvular curtains, it must also be remembered that in a certain proportion of cases the mitral regurgitation may be due to atheromatous changes in the curtains themselves.

THE PHYSIOGNOMY OF MITRAL DISEASE.

This is usually characteristic and is very well illustrated in some of the cases at present in the wards. Thus it is well demonstrated in Case 2, Case 4, Case 6, Case 8, and Case 9. In these cases the lips and cheeks are well coloured; the red colour of these features, however, is scarcely that of health, having a more or less livid hue, which is apt to become more pronounced on coughing or c exertion. The face also is sometimes rather puffy-looking and there is in the expression a suggestion of impaired breathing power. The physiognomy of mitral disease is thus generally in striking contrast with the marked pallor which so often prevails in cases of aortic regurgitation.

ASSOCIATION WITH ACUTE RHEUMATISM.

In six out of the ten cases summarised for the purposes of this lecture there is a definite and unmistakeable association with acute rheumatism—a proportion of 60 per cent. This association, however, may not always be in evidence before the onset of symptoms indicative of the presence of mitral disease. In Case 4 well-marked mitral obstruction and *regurgitation was known to be present at least a year* before the patient suffered from her first attack of acute articular rheumatism. She had, however, between the ages of five and six years suffered from chorea, and no doubt this is to be regarded as a manifestation of the rheumatic diathesis. It is noteworthy, however, that she had never suffered from acute articular rheumatism till her second admission to the ward on Oct. 14th, 1899, when she was 12 years of age. This is a feature of the rheumatic manifestations of childhood to which Dr. Cheadle first directed attention and which I have had frequent opportunities of demonstrating to my students in these wards. In the remaining four cases of the 10 there is only one in which acute articular rheumatism can be quite excluded—Case 8. In the other three cases two own to having suffered from "growing pains," or "rheumatics," so that it may be fairly concluded that acute rheumatism is the exciting cause of lesions of the mitral valve in from 60 to 70 per cent. of the cases.

THE PULSE OF MITRAL DISEASE.

The characteristic pulse of mitral disease is well illustrated in only two of the 10 cases. In these cases there is the well-marked irregularity in force and rhythm which is so typical. It is worthy of note also that this extreme irregularity of the pulse is often obtained comparatively early in cases of rheumatic mitral disease before any very marked symptoms of failing compensation have set in. Increased frequency of the pulse is a very common condition in mitral disease, and in five of the cases (Cases 3, 4, 6, 8, and 10) pulse-rates varying between 90 and 120 were recorded. This increased frequency of the heart's action in mitral disease is often very obstinate, and a reduction of the pulse-rate to the normal is not uncommonly one of the first indications of improvement under treatment.

THE SECONDARY RESULTS OF MITRAL DISEASE.

Secondary results are various and only those illustrated in the present series of cases need be referred to in closing this clinical lecture. Failing compensation, with its accompanying passive congestion of the lungs, liver, and kidneys and œdema of the lower limbs, is, perhaps, most to be dreaded. Fortunately, in only two of the cases—Case 3 and Case 8—is this exceedingly grave condition well marked. In all the other cases the compensation is fairly well maintained and the great aim of treatment must be to maintain it. Embolism is a frequent result of structural disease of the cardiac valves and, as in two of the cases—Case 7 and Case 10—this complication is most formidable when it occurs in one of the cerebral arteries. The last complication to which I will refer, that of hæmoptysis, is illustrated in only one of the cases—Case 10. Hæmoptysis is an exceedingly frequent occurrence in well-marked cases of mitral stenosis and it may occur repeatedly. I have frequently thought that it is not altogether to be regarded as a bad symptom, the frequently repeated attacks so often witnessed without serious results following being, perhaps, nature's method of relieving the greatly congested lungs.

Into a discussion of the great and vital question of the prognosis of mitral disease I do not intend to enter. The formulating of precise statements, if that is really ever possible, with regard to the future progress of cases of mitral disease demands an experience much greater than I yet possess. The principles of treatment have been explained in the course of our ward visits. My object in the present lecture has been to direct your attention to some of the more practical points connected with the physical signs and symptoms of mitral disease, in so far as these are illustrated by the cases at present under review.

MÜLLER'S ORPHAN HOUSES, BRISTOL.—The sixty-second annual report of this institution, which has just been issued, shows that 171 orphan children were admitted during 1900, and that 1435 remained in the homes at the end of the year. The average expense of each orphan per annum was £16 8*s* 5*d*. The financial statement was satisfactory and showed that from the foundation of the homes £1,066,943 had been received without anyone having been personally applied to for anything. Up to now only children bereaved of both parents have been eligible for admission, but it has been decided that children who have only lost one parent may be admitted in future.

THE COMPARATIVE VIRULENCE OF THE TUBERCLE BACILLUS FROM HUMAN AND BOVINE SOURCES.[1]

By MAZYCK P. RAVENEL, M.D.,

BACTERIOLOGIST OF THE STATE LIVE STOCK SANITARY BOARD OF PENNSYLVANIA; LECTURER ON BACTERIOLOGY, VETERINARY DEPARTMENT, UNIVERSITY OF PENNSYLVANIA.

(*From the Laboratory of the State Live Stock Sanitary Board of Pennsylvania.*)

THE relation existing between the various types of the tubercle bacillus found in man and in the lower animals has been the subject of much discussion for several years past, and studies of the morphology, biology, and virulence have been undertaken with the object of determining whether or not constant differences could be detected in the organism from these two sources sufficient to justify their classification as distinct species. From a purely practical standpoint the question is narrowed to a study of the bacillus as found in man and in cattle, and in the determination of the relation they bear to each other. The importance of this study is immense, not only to the physician anxious mainly for the protection of his patients, and to the general public who look to the medical profession for guidance in such matters, but perhaps even more so to those who are concerned in the framing of laws and direction of public measures looking to the suppression of tuberculosis in man and animals. Efforts in this direction often meet with strong opposition and extreme statements are made on very scanty evidence, which render the task of the hygienist much more difficult and may result in the failure of his purpose. The lack of positive and authoritative knowledge in regard to this matter has in recent years led to the adoption of retrograde measures in several places The problem is one that can be entirely cleared up only by a long series of observations and carefully conducted experiments, which are tedious and exacting and require a considerable lapse of time before results can be had The correct interpretation of these results is in many cases not an easy matter.

The identity of the tubercle bacillus as found in the mammalia went unquestioned for many years, and laws for the prevention of the transmission of the bacillus of cattle to man have been based mainly on this belief. In America Dr. Theobald Smith was the first to take up the systematic study of the bacilli isolated from various of the lower animals and man, and to call attention to certain fairly constant differences observed in the organisms from the two sources which he considers sufficient to justify classifying them as distinct varieties or races, though his experiments "show unmistakably the close relationship existing among the various cultures studied."[2] Dr. R. R. Dinwiddie,[3] pathologist and bacteriologist of the Arkansas Agricultural Experiment Station (U.S.A.), has carried out extensive experiments, in which he has compared the virulence of the human and bovine tubercle bacillus, and also human tuberculous sputum, with bovine material, for a number of the domestic animals, his results showing a greater power for both the bovine bacillus and material than for the human.

The vast practical importance of the matter, no less than its great scientific interest, was early realised by Dr. Leonard Pearson, State Veterinarian of Pennsylvania, and under his direction we have devoted much of our attention at the laboratory of the State Live Stock Sanitary Board for more than two years past to the study of the tubercle bacillus obtained from various cases of tuberculosis in man and in cattle. In the carrying out of this work I have had throughout the efficient assistance of Dr. S. H. Gilliland, on whom a large share of the labour has fallen, and to whom is due much of the credit in its successful issue To him and to the several physicians who have interested themselves in obtaining material for us I beg to express my obligation During a considerable portion of the time that Part (1) of the experiment was in progress Dr. W. O. Shaw was in charge of the animals and did much of the work, while the bovine material for the inoculations was obtained and prepared by Dr. J. J. Repp; both of these workers were at the time connected with the laboratory.

[2] Transactions of the Association of American Physicians, 1896.

[3] Arkansas Agricultural Experiment Station, Bulletin No. 57, June, 1899.

Our experimental work has been divided into two parts: (1) isolation and study of pure cultures from various sources in man and cattle; and (2) testing the pathogenic power of tuberculous material of human and bovine origin.

Under the first division 13 cultures, seven of human and six of bovine origin, are included in this report. Of these, two human and two bovine have been compared under conditions as nearly identical throughout as it was possible to obtain them. Culture H (bovine) and culture K (human) were isolated within a few days of each other, while L (bovine) and M (human) were made on the same day. The first sub-cultures of both pairs were made on the same day and all transfers since have been made simultaneously. The comparative pathogenicity of these cultures is shown in Table I. and Table II. Cultures H and K were tested also for puppies and pigs by feeding, as described below. Culture H was recovered from a horse, a goat, two puppies, two hogs, and a man; while Culture K was recovered only from two puppies and two hogs, the absence of lesions in other animals inoculated making it impossible to obtain a series comparable to Culture H. The virulence of these recovered cultures, with the exception of that from the horse, was tested for guinea-pigs and rabbits, the results being given in Table III. Human cultures I, J, U, and W, and bovine cultures F, Q, QQ, and T, were isolated as occasion arose, and their virulence tested only for guinea-pigs and rabbits. The dose and mode of inoculation were uniform in all cases and the animals were kept under the same conditions, but beyond this the tests are not entirely parallel. The results are given in Table IV. In addition to the cultures here mentioned we have isolated and examined nine others both morphologically and culturally. These have been taken into account in forming our conclusions, as well as the very careful descriptions given by Dr. Theobald Smith of the cultures studied by him. The terms "human" and "bovine" have been applied to cultures to denote their origin from man or from cattle. Each culture is designated by a letter of the alphabet, and the generation indicated by a small figure at the lower right corner. Cultures which have been inoculated and recovered retain their original letter, a second letter inclosed in brackets being added to mark the recovered culture.

The second part of the work has been the inoculation of animals with tuberculous material from man and cattle. The plan and methods are described in another section, while the results are given in Tables V. and VI. As a part of this experiment human tuberculous sputum has been fed to two calves and four have been inoculated with the same material. These have been included in Table V. and are described further on.

PART I.—ISOLATION AND STUDY OF PURE CULTURES FROM VARIOUS SOURCES IN MAN AND CATTLE.

Method of isolating pure cultures.—The isolation of cultures has been obtained by the method devised by Dr. Theobald Smith,[4] the principal features of which are as follows:—1. *Test-tubes* are fitted with a ground on cap like that of the well-known Miquel flask. The small tubulation in the cap is plugged with glass wool. 2. The medium is dog's serum. The animal is bled with the strictest aseptic precautions and the blood conducted to sterile jars through sterile rubber tubes. The serum is drawn off with pipettes and distributed at once into the test-tubes, put in the hardening oven, and coagulated at a low temperature (76° C.). Prepared in this way the serum needs no sterilisation and is much softer than when a higher temperature is employed. 3. The tubes are kept always inclined. 4. The tuberculous tissue selected for planting in our culture tubes is not crushed or rubbed over the surface, as advised in other methods. Young nodules from the omentum, spleen, liver, or a lymphatic gland are cut out and a block of considerable size is placed on the surface of the serum. After remaining from two to three weeks in the incubator at from 37·5° to 39° C. the tissue is pressed against the sides of the tubes with a stout platinum wire and rubbed over the surface of the medium. Examination of the fluid squeezed out of the tissue at this time will generally indicate the final result. The tubes are replaced in the incubator and within a week or 10 days colonies of the tubercle bacillus usually appear. The nodules for inoculation of the tubes are best obtained from guinea-pigs which are to be inoculated with the original matter from which we wish to obtain cultures. As soon as these show marked illness they are chloroformed and the cultures made. In general terms, the more recent the lesions the greater the chances of successful culture. As a rule, guinea-pigs can be killed in from three to four weeks after inoculation. If our material is of human origin the inoculation should be intra-peritoneal; if bovine, subcutaneous inoculation will generally cause a sufficiently rapid involvement of the organs. 5. The incubator should contain a dish of water to insure an abundance of moisture in the atmosphere. With the same object in view it should be opened as seldom as possible. The only modification of the above method in our work has been the addition of a 50 per cent. solution of glycerine in water to the serum in such proportion that the resulting mixture contains 5 per cent. of glycerine. This seems to make coagulation slightly more tardy, but the serum does not dry as quickly, and the growth of the tubercle bacillus is facilitated. Serum prepared in this manner has been employed throughout for the cultures used in our inoculations.

Preparation of cultures for inoculation and dosage.—The course of an experimental tuberculosis depends so largely on the number of bacilli introduced that exact dosage is an important factor in comparative work. Weighing naturally suggested itself, but a trial soon convinced us of its impracticability. The growth of human cultures is usually so abundant by the second generation that it is easy to obtain fairly dry masses which can be weighed quite accurately, but bovine cultures often grow very scantily for many generations as a thin film resembling ground glass. We have adopted as a uniform practice the method of Dr. Theobald Smith—the use of a suspension of a given opacity. A portion of the growth is removed to the wall of a dry and sterile test tube and rubbed round and round with a glass rod until no lumps can be seen. Bouillon is then added and after stirring thoroughly the mixture is allowed to stand quiet for two or three hours so that the clumps may settle. The upper portion is poured off and bouillon added until the suspension equals in turbidity a 24-hour old culture of the typhoid bacillus. The test culture is killed with formalin vapour and sealed so that it can be used as a standard for a considerable time. Cover-glass preparations were made always as controls. In the accompanying tables the generation of the cultures is indicated by the exponent and the age of each culture is given in days in a separate column. For guinea-pigs and rabbits the dose has, throughout, been one cubic centimetre of the suspension introduced under the skin of the abdomen. For the other animals the dose and mode of inoculation are given in the tables.

Morphology and cultural characteristics of bacilli examined.—The morphology of the bacilli in cultures of bovine origin is more uniform and constant than in cultures from man. The bovine bacilli are short, seldom more than two microns in length and averaging less. In early generations many are seen which are oval, their length not more than double their breadth. They are thick and straight. They stain with carbol-fuchsin evenly and deeply and beading is markedly absent, even in old cultures. The human bacilli are, as a rule, much longer from the start and tend to increase rapidly in length in sub-cultures. They are generally more or less curved and some cultures contain many S-shaped forms, as culture M noted below. They stain with carbol-fuschin less deeply and beading is a marked characteristic, often seen in the earliest growth. These characteristics are most persistent in cultures on blood serum. On glycerine agar, glycerine bouillon, and potato with glycerine the bacilli from the two sources approach each other in appearance and morphology much more closely.

The human cultures isolated have without exception grown more luxuriantly than the bovine cultures, though in at least two instances (Culture U and Culture BB) the first growth was very long in appearing. This was due no doubt to their feeble virulence and consequent slow production of lesions in the tissues of guinea-pigs. A saprophytic life once established they grew vigorously. The bovine cultures are apt to grow as discrete colonies in the first culture and for several generations are likely to grow as an exceedingly thin layer over a part of the medium, resembling closely ground glass. The human bacillus can usually be induced to grow on glycerine agar in sub-cultures made from the original growth on blood serum. All attempts to obtain a like result with

the bovine organism have failed. Three of the bovine cultures examined have been isolated from milk. Two of them, Culture L and Culture Q, have shown throughout the characters of the type described as "bovine," while T approaches the human bacillus in morphology, being long and slender. It is, however, more virulent than any human culture tested.

* Killed Oct. 4th.

Among the human cultures only one (M) has been isolated from sputum. Through the kindness of Dr. Alfred Hand, pathologist of the Children's Hospital, to whom I beg to make grateful acknowledgments, I have been able to obtain cultures from three cases of tuberculosis in young children in which the intestine was involved. One of these, from which Culture BB was isolated, was considered by Dr. Hand to be "more clearly than any other he had ever seen, of intestinal origin," and was therefore studied with peculiar interest. Its pathogenicity has not yet been determined, but the course of the disease in the guinea-pigs inoculated to obtain the culture indicated a very feeble virulence, one living 66 and another 96 days. The bacilli, even in the first generation, are unusually long and thick. They stain deeply with carbol-fuchsin, but are beaded in a striking manner, the brightly stained portions being quite regularly disposed along the rod. They are, in every way, most unlike what I have described as the bovine type. Cultures U and W, also from children with intestinal lesions, correspond to the human type in every particular, both as regards morphology and virulence.

The following is the comparison and history of Culture H (bovine) and Culture K (human) :—

Culture H (bovine) was isolated from the mesenteric gland of a Jersey Grade cow about seven years old which had been slaughtered for beef but being found to be extensively diseased was condemned The lungs were the seat of an extensive and long continued [illegible] had undergone caseation [illegible] he foci [illegible] but to a less extent The gland [illegible] the culture was obtained had undergone cheesy degeneration On May 17th, 1899, guinea-pigs were inoculated intra peritoneally with an emulsion made from the centre of this gland On July 6th one pig was killed and cultures were made on dog's serum On July 28th the first growth was observed, and on August 18th sub cultures were made from the omentum The growth was fairly abundant The bacilli were short, thick, straight, and stained evenly and deeply Culture K (human) was isolated from the lung of an adult male negro The disease was not severe and was confined almost entirely, to the lungs Death was due to heart trouble Guinea pigs were inoculated intra peritoneally with an emulsion made from nodules taken from the lungs on June 10th 1899 On June 28th a pig was killed and cultures were made on dog's serum Growth was first observed on July 29th the cultures from the spleen being used for sub cultures, the first of which was made on August 18th This culture grew rapidly and abundantly from the beginning. The bacilli were long slender, and curved They stained somewhat faintly and showed marked tendency to beading (See Table I)

The following is the comparison and history of Culture L (bovine) and Culture M (human) :—

Culture L (bovine) was obtained from the milk of a cow with tuberculosis of the udder On May 22nd, 1899, a guinea pig was inoculated with 10 cubic centimetres of this milk It died on July 8th and from it a second guinea pig was inoculated intra peritoneally with an emulsion made from the spleen and omentum On August 25th this pig was killed and two others were inoculated intra-peritoneally with an emulsion from [illegible] killed on Sept [illegible] On Oct 20th gr[illegible] On Nov 17th sub-cultures were made The growth for several generations was very scanty The bacilli were extremely short and many were oval in shape They took the stain evenly and deeply Culture M (human) was obtained from the sputum of a young adult female Throat symptoms were not marked in this case The disease was rapid and virulent, death occurring in about five weeks after the sample of sputum was obtained It contained large numbers of tubercle bacilli On July 12th 1899 a guinea pig was inoculated subcutaneously with the sputum It was killed on August 25th and two pigs were inoculated intra peritoneally with an emulsion made from the spleen and omentum On Sept 18th a pig was killed and cultures were made on dog's serum Growth was first observed on Oct 15th and sub-cultures were made on the 17th Growth was rapid and abundant from the outset and the first transfers made from the original culture [illegible]

agar grew luxuriantly. The bacilli in the original culture were rather short, irregular in shape, many S-shaped, and as a rule stained quite evenly and deeply. In sub-cultures the bacilli soon became much longer, straighter, and showed beading (see Table II.).

It will be seen from Table I. and Table II. that for each culture 10 animals were used. Of the 10 inoculated with Culture H (bovine), nine died, while only one had to be killed, this being the horse; while of those inoculated with Culture K (human) only three died, while seven had to be killed. With each of Culture L (bovine) and Culture M (human) eight animals were inoculated. Of those inoculated with Culture L six died and two were killed, while for Culture M four died and four were killed. Taking the totals of these four cultures, 18 animals were used for the bovine cultures and 18 for the human. Of those inoculated with bovine tubercle bacillus 15 died and three were killed, while of those inoculated with the human cultures seven died and 11 were killed. By making a closer study of the tables further differences in virulence between the bovine and human cultures may be brought out. All the guinea-pigs inoculated with these four cultures died, the extent of the post-mortem lesions being practically identical in all of them. Those inoculated with Culture K (human) lived almost 10 days longer than those inoculated with Culture H (bovine), while those inoculated with Culture M (human) lived seven and a third days longer than those inoculated with Culture L (bovine). All the rabbits inoculated with both of the human cultures had to be killed and showed no post-mortem lesions whatever, while those inoculated with the bovine cultures died with extensive lesions. These lesions varied somewhat in the different animals, necrotic areas at the point of inoculation and complete involvement of the lungs being common to them all. The kidneys were also generally involved. Only one animal had generalised tuberculosis, involving the lungs, liver, kidneys, spleen, and omentum.

Dogs.—The dogs showed a varying degree of susceptibility to all the cultures. Both of those inoculated with Culture H (bovine) died, one in 59 days, the other in 66 days. The smaller of the two had shown signs of illness for some days before death. The point of inoculation was well marked in the lung by a mass of tubercles 2·5 centimetres in diameter. Both lungs were infiltrated throughout with grey nodules from two millimetres to four millimetres in diameter. Both pleural cavities contained a considerable amount of purulent effusion. The right pleura was roughened, without adhesions. The outer surface of the pericardium was thickly sown with minute nodules about two millimetres in diameter, its interior being smooth. The liver was infiltrated throughout and necrotic, giving a nutmeg appearance. The right kidney contained a number of tuberculous nodules; the left was congested but otherwise normal. The spleen had escaped infection. Through an accident no post-mortem examination was obtained on the other dog, but from his symptoms for some days before death it is reasonably certain that the disease was general, affecting particularly, perhaps, the lungs. Both of the dogs inoculated with Culture K (human) had to be killed, the lesions in both being insignificant. In one the only marked change which could be found corresponded to the point of inoculation in the lung, where a small excavation was found almost completely filled in with scar tissue, radiating from the centre in star shape. Scrapings from cut surfaces of this area revealed the presence of tubercle bacilli. All the other organs were entirely normal. In the other dog the point of inoculation was marked by a large nodule in the pleural surface of the lung. The surfaces of both lungs showed a great number of minute nodules. Scrapings from cut surfaces revealed tubercle bacilli in small numbers. On the external surface of the pericardium was a nodule about one inch in diameter, which contained calcareous foci encapsulated in dense fibrous material. The mediastinal glands were enlarged and contained a number of caseous foci. In all other respects the animal seemed normal.

Horses.—A marked difference was noted in the effect of the cultures on the horses. The horse inoculated with bovine Culture H showed no ill-effects from the injection for some months. In the latter part of March, nearly four months after the injection, some emaciation could be noted, and the respiration was quickened, being on an average 22 a minute and somewhat laboured. On April 1st the temperature averaged 102 2° F. The symptoms grew slightly more marked, and on June 25th, six and a half months after inoculation, the animal was killed. It had lost 40 pounds in weight, though its condition was still fair. The costal pleuræ were extensively covered with masses of nodules of from two millimetres to 18 millimetres in diameter, averaging nearly 12 millimetres in thickness. These growths were somewhat more extensive on the left side than on the right and tended to be more isolated and somewhat larger in size. The lungs were a greyish pink, the blood-vessels being plainly outlined in a delicate network over the surface. They were covered with nodules, varying from one millimetre up to six millimetres in size and closely packed. Both lungs were hard, dense, and devoid of elasticity, having much the feel of liver. At the point of inoculation on the right lung a small depression was found filled in with a star-shaped cicatrix. This cicatricial tissue was surrounded with a nodule about 2·5 centimetres in diameter, containing cheesy areas and much fibrous tissue. In the posterior part of the left lung a tuberculous abscess about 2·5 centimetres in diameter was found, and in the bottom of the lung several similar in size and character were seen. The bronchial glands were enlarged to twice their normal size but showed no caseation. The surface of the pericardium was studded with minute nodules. The thoracic surface of the diaphragm was covered over a large portion of its surface with nodules of the size of a pea, some of them pedunculated. Among the nodules were many shreds of fibrin, some of them 2·5 centimetres in length. Similar masses were seen also on the costal surface of the lung. The liver, spleen, and kidneys appeared normal. The horse inoculated with culture K (human) showed no clinical evidence of injury. On April 1st its respiration was 12 a minute and its temperature was 100·5° F. It was killed on June 25th, about six and a half months after inoculation. Its condition was good. It had gained 95 pounds in weight. There was considerable fat subcutaneously and about the abdominal organs. All of the abdominal organs were entirely normal with the exception of the liver, on the surface of which many fringes of fibrin were found. In the thoracic cavity both pleuræ were smooth and shiny except at the point of inoculation on the right side, where a mass of small nodules with fringes of fibrin were seen. At the point of inoculation in the right lung was a cheesy abscess 4 centimetres in diameter, and incapsulated with dense fibrous tissue, the walls being 6 millimetres thick. Otherwise the lung was entirely normal. In the left lung were three small tuberculous nodules about 12 millimetres in diameter, situated near the surface; these had undergone caseation. The disease was evidently non-progressive and was probably retrogressive.

Goats.—Both the goats inoculated with Culture H (bovine) died, one in 22 days and the other in 26 days, the lesions being much the same in both. There were thickening of the pleura and adhesions at the point of inoculation; otherwise they were normal. The lungs were covered with myriads of minute tubercles about one millimetre in diameter, which gave a gritty feel to them. In the substance of the lung no tubercles could be found. The cut surfaces presented a pneumonic appearance, most marked in the smaller of the two animals. Scrapings from a cut surface in any portion of the lung revealed enormous numbers of tubercle bacilli. The mucus in the bronchial tubes throughout the lungs also contained large numbers of tubercle bacilli. In the larger animal the liver, spleen, kidneys, peritoneum, and diaphragm were normal. The animal lost 18 pounds in weight in the 22 days of its life after inoculation. The smaller goat showed involvement of the abdominal organs also. The omentum was studded with pearly tubercles two millimetres in diameter, one of which had undergone caseation. The surface of the spleen was thickly covered with tubercles one millimetre in diameter. In the substance of the spleen no nodules could be found, but scrapings from cut surfaces showed a large number of tubercle bacilli. The liver showed no macroscopic tubercles, but scrapings from cut surfaces were rich in bacilli, and in sections under the microscope tubercles were seen with a few giant cells. Microscopic examination of the lungs, however, revealed no tubercles. The infection in this animal was diffuse and it is considered to be a case of tuberculous septicæmia. Both of the goats inoculated with Culture K (human) gained in weight and were killed after six months and 21 days. Both were in good condition, having a considerable amount of fat in the subcutaneous tissues and around the abdominal organs. In the larger animal at the *point of inoculation there was an area of adhesion to the* pleura about eight millimetres in diameter. On the surface of the left lung were two or three nodules about three millimetres in diameter which had undergone caseation. This lung is attached at its lower edge to the diaphragm by fringes of fibrin, and along this edge a few nodules about 12 millimetres in diameter and containing cheesy pus were found. The entire surface of the left lung was covered with fringes of fibrin of a reddish pink colour. In both lungs the elasticity was preserved and neither revealed nodules either by palpation or on section. The left pleura was covered with a network of fibrin similar to that seen in the lung; the right was normal. The mediastinal *glands were much enlarged and calcareous.* In the liver two small nodules were found near the surface, the organ being otherwise normal. In the smaller animal the omentum contained upwards of 100 nodules from two to 12 millimetres in diameter. The left lung was attached to the pleura at its edge by numerous bands of fibrin and at its posterior surface to the diaphragm in the same manner. Along the lower border were a number of nodules about six millimetres in diameter which had undergone caseation. The right lung was normal. The mediastinal glands were enlarged and calcareous. The left pleura showed 10 or 12 nodules six millimetres in diameter, which were cheesy, besides a large one corresponding to the point of inoculation. The diaphragm was attached *to the spleen and* to the stomach by bands of fibrin but no nodules were found. The liver was normal; the portal glands were enlarged and contained many cheesy nodules. The left kidney contained a number of cheesy nodules. The right kidney was normal. The mesenteric glands were enlarged and several of them contained calcareous areas.

The comparative virulence of Culture H (bovine) and Culture K (human) for puppies and pigs when introduced through the alimentary tract was as follows:—

Puppies.—Four puppies eight weeks old, from the same litter, were selected; two of them received a suspension in milk of Culture H (bovine) and two a similar suspension of Culture K (human), equal amounts being given on 10 days—six days in succession, with an interval of seven days, then four days in succession. The regular food was sterilised milk, bread, and boiled beef. Only one of the four puppies died—the one which received Culture K (human)—death occurring after 57 days. There was a generalised tuberculosis most marked in the lungs and liver. The other puppy of this pair was killed after 65 days. The only lesions found were small cheesy nodules on the surface of one lung, in the parotid and mesenteric glands. The two puppies fed with Culture H (bovine) showed no ill effects whatever and were killed on the eighty-fifth and eighty-seventh days respectively. Both were in good condition, the only lesions found being in the parotid and mesenteric glands, which contained minute caseous areas, none larger than 2 millimetres in diameter.

Pigs.—As with the puppies, four pigs from the same litter, eight weeks old, were taken, two being fed with Culture K (human) and two with Culture H (bovine), equal amounts of a suspension in sterile water being soaked into bread and given for 10 days, with an intermission *of only one day.* The regular food was sterilised milk, ground oats, bran, and corn meal. All four of the pigs died, the average life of the two fed with human bacilli being 118½ days, as against 100¼ days for the two which received the bovine culture. One pig of each pair lived 123 days, dying on the same day. The total difference in gain of weight was only half a pound. All showed post mortem a generalised tuberculosis. While some differences were noticed in the extent of the disease in various organs it cannot be said that these were such as to indicate a greater virulence of one culture than the other. In all the mesenteric glands were extensively diseased, while in one only, fed with bovine bacilli, was there ulceration of the mucous membrane of the intestine. Three of the four showed tuberculous ulceration of the tonsils. The remaining one presented no gross changes in this gland but microscopically areas of necrosis apparently in the lymph follicles were found and sections stained with carbol fuchsin revealed large numbers of tubercle bacilli. The two pigs which lived longest, one of which had received bovine culture and one human culture, both had extensive involvement of the joints, so that for several weeks before death walking was almost impossible.

The result of this experiment is inconclusive as far as the puppies are concerned except as showing that they are readily infected through the alimentary tract. The pigs *showed practically an equal susceptibility to the two cultures.* The ease with which they were infected and the extent of the lesions produced in so short a time were both most striking features and should serve to put farmers on their guard against feeding their swine on milk from tuberculous cattle. In Pennsylvania we have observed several instances in which neglect of this precaution has led to considerable loss.

The cultures included in Table III. were all recovered from animals which had been inoculated or fed with Culture H and Culture K. Their virulence was tested only for rabbits and guinea-pigs. The most striking thing to be noticed in the results is the increase in virulence in the human bacillus *recovered from the hogs K (D) and K (E).* The average length of

original Cu

after eight

infection

hogs killed guinea-pigs in 29½ and 32½ days and rabbits in 71½ and 62½ days respectively, showing a virulence for these animals which corresponds to that seen in bovine cultures. Culture H (F) was recovered from a nodule on the hand of Dr. S. H. Gilliland who accidentally inoculated himself while making a post-mortem examination of one of the goats which had succumbed to the original Culture H. Particular interest attaches, therefore, to this culture. No marked *difference can be detected in the virulence of this culture as* compared with the original. Considerable difference has been noted in the readiness with which the recovered cultures grew in the early generations. Cultures H (A), H (B), H (D), and H (E) all grew vigorously from the start, the last three growing without any stirring of the tissue on the original tubes, while Culture H (G) grew on tubes sealed with paraffin, a result which I have been able to obtain only with the human bacillus with this exception. The morphology of all the recovered cultures corresponded closely to the original.

The following is the comparison and history of other human and bovine cultures (see Table IV.):—

Culture F (bovine) was obtained from a large tumour on the diaphragm of a cow which had been slaughtered for beef. The tumour was 13 centimetres long and from seven to nine centimetres in diameter. On the surface were a number of grape-like masses of pearly lustre. On section numerous caseous areas were found from which an emulsion was made. It contained many tubercle bacilli. A guinea-pig was *inoculated intra-peritoneally* May 18th, 1899. Death occurred on June 6th and from tissues a second pig was inoculated intra-peritoneally. This pig was chloroformed July 31st and a third pig inoculated in the same manner; this third pig was chloroformed August 21st and cultures were made from the spleen and omentum. Scanty growth was observed on Sept. 27th. Under the microscope the bacilli were thick, short, and showed little tendency to beading, staining deeply and uniformly. The further history of this culture is given in the paragraph on "*Retention of* Characteristics in Culture."

Culture Q (bovine) was obtained from the lungs of a cow, No. 5986. This cow was brought to our department on July 6th, 1898, for experimental purposes, being considered then to be in an advanced stage of tuberculosis. The animal was emaciated and coughing badly. Many tubercle bacilli were found in the mucus it coughed up; they were long, thin, and much beaded. The animal died Feb. 12th, 1900. The lungs were infiltrated throughout, many of the areas having undergone caseation and calcification. It was difficult to understand how the animal had lived as long as it did. The mediastinal glands formed a tumour 35 centimetres long by 15 centimetres in diameter which was cheesy on section. The mesenteric glands were enlarged and cheesy. A guinea-pig was inoculated in the peritoneal cavity on Nov. 15th, 1899. On Nov. 30th the animal was killed and cultures were made. Growth was observed first on Jan. 10th, 1900, and sub-cultures were made on the same date. Growth was always scanty.

Culture QQ (bovine) was obtained from the mesenteric gland of cow No. 5986. An emulsion from the centre of the gland was inoculated into the peritoneal cavity of a guinea-pig on Feb. 13th, 1900. On March 5th it was chloroformed and cultures were made. Growth was observed on April 12th and sub-cultures were made on April 17th. Growth was more abundant than that of the preceding culture (Q), but still scanty.

Culture T (bovine) was obtained from milk sent in for examination by a dairyman in Philadelphia. It was inoculated into the peritoneal cavity of a guinea-pig Jan. 24th, 1900. The guinea-pig was chloroformed on April 6th. With an emulsion of its spleen two other guinea-pigs were inoculated intra-peritoneally on the same date. One of these was chloroformed on April 28th and cultures were made. Growth was observed first on June 23rd and cultures were made the same day. Growth was abundant and luxuriant.

Culture U (human) was obtained from a child, three years of age, whose death was due to tuberculous meningitis. At the necropsy the lungs and bronchial lymphatic glands were full of miliary tubercles. The anterior mediastinal glands were much enlarged. The spleen was extensively involved, but the liver less so. On the abdominal surface of the diaphragm were a number of flat yellow nodules. The mesenteric glands were enlarged and contained old yellow, cheesy nodules. One small tubercle was found in the right suprarenal body. Purulent and cheesy nodules were found in the meninges and in the encephalon. The culture was obtained from the mesenteric glands. The pathologist, Dr. Hand, was uncertain as to the origin of this case. Guinea-pigs were inoculated intra-peritoneally on June 15th, 1900. One was killed on July 23rd and with its tissues a second was inoculated intra-peritoneally. This was chloroformed on Sept. 12th and cultures were made. On Oct. 11th, no growth having taken place, the blocks of tissue were transferred to fresh serum and stirred. On Dec. 4th growth was first observed and on Dec. 15th sub-cultures were made. Growth has since been rapid and abundant.

Culture W (human). Obtained from a child nine months old, of scrofulous parentage. The cervical glands on both sides were enlarged. At the necropsy a double broncho-pneumonia was found. One small tuberculous nodule was found on the surface of the left lung and several at the apex of the right lung. The bronchial glands were not enlarged. The tonsils were normal in size, but the glands on each side of the pharynx extending in front of and behind the sterno-mastoid muscle were enlarged and tuberculous, and several contained creamy pus. Three mesenteric glands were enlarged and cheesy; an ulcer was found in the jejunum and another at the ileo-cæcal valve. Peyer's patches and the lymphatic glands about the cæcum were enlarged. The spleen and the liver contained tubercles. The mesenteric glands were employed for the isolation of the culture. This case was considered by Dr. Hand as being probably of tonsillar or pharyngeal origin. Guinea-pigs were inoculated intra-peritoneally on Oct. 5th, 1900. From one which died on Jan. 4th, 1901, a second was inoculated intra-peritoneally. This was killed on March 4th and cultures were made. Growth was first observed on April 12th and sub-cultures were made the following day.

Culture BB (human) was obtained from a child 17 months of age. Death was due to tuberculous meningitis. At the necropsy the lungs were normal, except the posterior and part of the right upper lobe, which was consolidated, red on section, and had excess of connective tissue. The bronchial and mediastinal glands were not enlarged. The spleen, the liver, and the kidneys showed pearly tubercles. Two feet from the lower end of the ileum was an ulcer one centimetre by two centimetres, the long diameter of which was transverse to the axis of the gut. Nodules were seen on the peritoneal surface. Four small ulcers, two above and two below, were found in the ileum. The mesenteric glands were enlarged and cheesy and some were purulent. The meninges showed yellow tubercles, most marked along the longitudinal fissure, in the choroid plexus, and over the cerebellum. The mesenteric glands were used in obtaining the culture. This case was considered by Dr. Hand to be the clearest one of primary intestinal tuberculosis ever seen by him. Guinea-pigs were inoculated intra-peritoneally with an emulsion made from the mesenteric glands on March 9th, 1901. One was chloroformed on April 1st and cultures were made. Scanty growth on one tube was found on June 8th and sub-cultures were made.

The results given in Table IV. show for all the bovine cultures a greater virulence than for any of the human cultures. The average life of the guinea-pigs inoculated with human bacilli was more than twice that of those inoculated with bovine. All the rabbits which received human cultures gained in weight and had finally to be killed, while for the bovine they died, and presented, post mortem, extensive lesions, the lungs and kidneys being the chief seats of the disease in all animals.

(To be continued.)

THE MORTALITY FROM PHTHISIS AND FROM OTHER TUBERCULOUS DISEASES CONSIDERED IN SOME ASPECTS WHICH MAY BE DEMONSTRATED BY MEANS OF LIFE-TABLES.[1]

BY T. E. HAYWARD, M.B. LOND., F.R.C.S. ENG.,
MEDICAL OFFICER OF HEALTH OF HAYDOCK, LANCASHIRE.

HERE are gathered together those who are most competent to make clear the conditions under which the battle is raging between tubercle bacilli and the human race, to explain how these, it may be, originally saprophytic fungi have acquired the power of existing in, and preying upon, living animal bodies, and under what circumstances these latter may have their vital resisting power so lowered that they fall a readier prey to their assailants. Here also are those who by position and capacity are best able to plan and to arrange details of sanitary administration which shall give effect to the scientific knowledge laboriously attained by those who have made study of life and disease. Others, too, are here who in various ways have sought to throw light upon the problems involved by means of statistical methods. There is need on a field of battle for some to be told off to count the numbers of the killed and wounded, and without unduly exalting the position of statisticians it may be claimed that those who in the past as well as at present have been working at vital statistics have had some share in awakening the great public interest and attention of which this Congress is the outcome. Exact representations of the numbers of the living who year by year are being cut off by the germs of tuberculosis, together with gradually increasing certainty that phthisis and other tuberculous diseases are to a very large extent *preventable*, have brought together this great assembly. The simplest mode of statistical representation, of course, is merely to show how many die out of so many living. The next step in advance is by classifying the living population and the deaths into age and sex groups to show the special incidence of the mortality from some particular disease in the respective sexes, and at different periods of life. But instead of asking how many die from a disease out of a thousand or million living we may ask, supposing that this disease could be made extinct, *how many more would be alive at certain ages and how much longer would they live?* Now these questions can be answered by means of life-tables.

In some respects this Congress is being held at an unfortunate time. A year hence it might have been possible to utilise the data of the census recently taken and also the tabulated mortality for the decennium just completed, 1891–1900, and so to have obtained results brought down to a very recent period. As it is we have to go back to the numerical facts relating to the decennium 1881–90. What I propose to do is to show how the life-table for England and Wales for 1881–90 would have been affected supposing there had been during the period no deaths from phthisis or from the other tuberculous diseases, and that all the other causes of mortality had retained their proportional intensity. This is, of course, a mere hypothesis, but it is a necessary working hypothesis. It is possible that the extinction of one kind of disease germs might leave room for the more active development and diffusion of other kinds, but we can only work on the assumption already made that if some one disease should be eliminated those saved from dying from it will be exposed to the chances of all other diseases in the same proportion as before, and that their average exposure to these chances will be for half the year. This is not the time or place for going into details as to what a life-table is or how it is constructed. Such knowledge has to be assumed as possessed by those addressed. I would, however, desire to emphasise the fact that the work of constructing a complete or "extended" life-table—that is, one for every separate year of life—entails an enormous amount of laborious calculation, and that if the object be to have not merely one life-table but a series of life-tables to compare with each other it is practically impossible for one unaided individual to undertake the labour of doing the work by an extended method. The existing duration of life is too short—one would need to be a Methuselah. Even the late Dr. William Farr, with his untiring industry and with the advantage of a staff of trained calculators to help him, employed for the purpose of some comparative life-tables, based on the mortality of England and Wales, for the decennium 1861–70, which were published in the Supplement to the Thirty-fifth Annual Report of the Registrar-General, a short or abbreviated method, details of which are given in the same supplement. Another point which I would wish to lay special stress upon is that, in order to be fairly comparable with each other the life-tables must be calculated by the same method. If the occasion permitted I could give ample proof of this by comparative figures, worked out from the same data by different methods Now, in some experimental work on life-table calculation I happened about three years ago to hit upon some very simple modifications of Dr. Farr's original method of constructing a short life-table, which gave results approximately to those of an extended life-table with remarkable closeness [2] By this method the expectation of life can be

---

[1] A paper communicated to the British Congress on Tuberculosis. Section I., State and Municipal.

TABLE I.—*Comparison of Life-table Results as regards Mean Expectation of Life obtained by (a) an Extended Method, and (b) the Modified Short Method used in the Construction of the Succeeding Tables* *

A.—Expectation of Life or Mean after Lifetime at exact age x.

Age.	Males.			Females.		
x.	a.	b	Differences of b from a.	a.	b.	Differences of b from a.

[2] For a description of the methods and for comparative figures in illustration and proof reference may be made to Public Health, vol. xi., page 330, July, 1898, and to the Journal of the Royal Statistical Society,

calculated at quinquennial age-intervals, with results differing by only from 0 01 to 0·10 of a year, from the result obtainable by what I believe to have been the most accurate extended method—that is practically only varying to the extent of from a few days to a few weeks. *Indeed, the results approximate much more closely than do those obtained by extended life-tables worked out by different methods.* It has been, perhaps, necessary to say so much in support of the claim to be made that the method which has been adopted in working out the appended tables is a sufficiently accurate instrument for statistical research. Table I., with its three divisions—A, B, and C—is intended to illustrate and support this preliminary claim. What has been hitherto published of the references already given has relation only to the results in division A; certain other simple devices, by which the short method may be made to yield the results set down in divisions B and C, have occurred to me while engaged in preparing this communication. At some time ere long I hope to publish the details of the arithmetical methods employed. The other tables will to a large extent be left to speak for themselves. The data upon which the calculations have been made are to be found in the Annual Report and Decennial Supplements of the Registrar-General. As it seemed desirable to make at least one comparison with an earlier period I have prepared Tables II. and III., which are intended to demonstrate the effect of excluding phthisis as a cause of mortality in England and Wales during the 10 years 1851–60. Table II. is one of a series as yet unpublished. Table III. has the same relation to Table II. as Table V. has to Table IV. The comparison serves to further illustrate what already was evident by the ordinary death-rate—that the mortality from phthisis has much diminished. Some of the decrease may be, of course, only apparent—we have to consider the less accuracy of diagnosis at the early period and also possible cyclical variations in the intensity of the disease; but the opinion is at least very generally held that a large proportion of the lessened mortality is real and is the result of improved sanitation and bettered conditions of life. Attention may be specially directed to the altered sex incidence of this disease, the mortality being greater among females in 1851–60, from age two to age 35, whereas, except at ages four, five, 10, and 15, during 1881–90, it was greater among males. The remaining Tables relate to the 10 years 1881–90. Tables IV., V., and VI. afford answers to these three questions—supposing that (1) phthisis and (2) the whole group of tuberculous dieases had had no existence as causes of mortality in England and Wales during 1881–90, at each of the ages indicated respectively—(*a*) how much greater would have been the chance of surviving to the end of one year? (*b*) how many more would be living at each age? and (*c*) how much greater would be the mean expectation of life, or, in other words, the mean after-lifetime of each age? With regard to the *lx* columns—that is, the successive numbers of survivors at age *x*—it must be borne in mind that the results of the short method are more and more in excess of those obtained by the extended method from about 25 years of age onwards. However, as the three Tables IV., V., and VI. are worked out by the same method the results are fairly comparable in their proportions to each other. The *Ex* columns are of the greatest importance, and these, as has been shown, are practically identical with those to be obtained by the extended method. The fact which stands out from all

Vol. lxii., parts 3 and 4, September and December, 1899. My friend Dr. A. Newsholme has also done me the honour to insert a description of this method in the last edition of his well-known work on "Vital Statistics" (see Chapter xxiii., page 279).

others is that *if there had been no phthisis the average length of life for each individual born would have been increased by two and a half years.* Another prominent fact is that those who have survived to the age of 15 years would have their average expectation of life increased by about three and a quarter years. Now these hypothetical results are greater than those which would be obtained by abolishing the whole group of ailments classed together as "the seven principal zymotic diseases." As regards the three diseases to combat which the expensive machinery of isolation hospitals chiefly exists—viz., typhoid fever, scarlet fever, and diphtheria—if they could be entirely exterminated the average increase in length of life of those at birth would only be increased by about a year, and those at age 15 would only have about the fourth part of a year to add to their life expectation. Table VI brings out prominently the fact that the group of tuberculous diseases other than phthisis exert their maximum efforts at the earlier ages of life, these being more marked during the first five years, and after 15 years becoming comparatively insignificant. There is another aspect, however, under which the increased length of life brought about by doing away with phthisis may be considered. It has been seen from Table V. that those at the very outset of life would on the average have two and a half years longer to live. Now it is of importance to ascertain, if

TABLE VII.—*Showing how the Increased Expectation of Life at Birth represented in Table V. as produced by Eliminating Phthisis, would be Distributed over the Periods of Life indicated, and also a comparison with a similar Distribution of the Expectation of Life at Birth calculated in Table IV.*

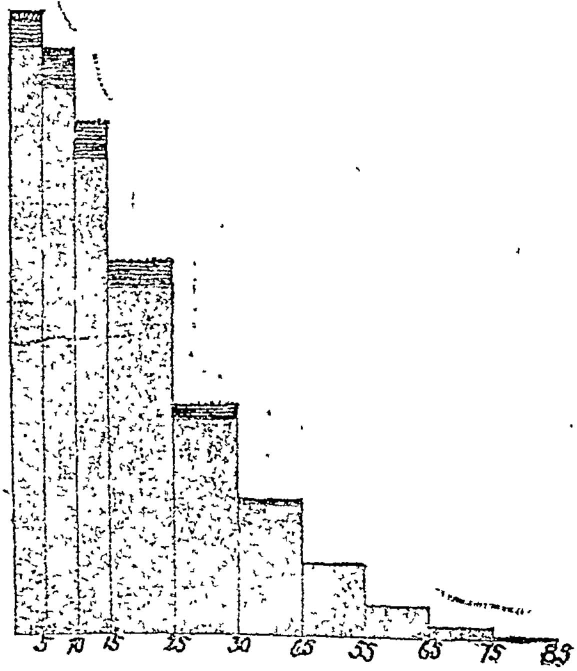
[illegible] given in the [illegible] the census [illegible] estimated [illegible] year 1891. [illegible] Table IX. [illegible] will [illegible] possible, how much of this added life would be lived during the part of life extending from age 15 to age 65, which may be considered as the working period of life? This question is answered by Table VII., which shows that the *working period of life would be lengthened on the average by very nearly two years.* The matter may be illustrated in yet another way. The *Ex* values in Tables IV., V., and VI. apply to those *at the exact age x*, but if these values can be translated into those applying to age-groups, that is, into average values of expectation of life with relation to all the individuals at all ages from x to $x + n$ comprised within the respective age-groups x to $x + n$ (for example, from birth to age five, from age five to age 10, &c.), we shall then have a ready method of calculating what has been happily termed the "*Life-capital*" of a whole community. In Table VIII. such values have been worked out, and in Table IX. they have been used to show what was the total life-capital of the population of England and Wales as it existed at the middle of the year 1891, and to what extent the life-capital would have been increased (1) by abolishing phthisis and (2) by doing away with all other tuberculous diseases. A diagram also represents the results graphically to scale. However, the one striking and outstanding fact, which cannot be emphasised more than by the mere statement of it, is that if phthisis had not existed as a cause of mortality in England and Wales every person living in the year 1891 would have had an average increase in life-capital of two years, and that the abolition of all other tuberculous diseases would only have increased the average life-capital by the fifth part of a year.



The areas of the parallelograms represent to scale the life-capital of the respective age-groups numerically stated in Table IX. The columns indicate the life-capital deduced from Table IV. The transversely marked tops to the columns indicate the increase of life-capital after excluding phthisis. The vertically marked tops to the columns indicate the still further increase of life-capital after excluding all other tuberculous diseases.

The question may now be asked, Are there any practical conclusions and deductions to be drawn from the statistical points which it has been sought to establish and to represent? Now years of human life are capable of being translated into terms of pounds, shillings, and pence, and it is evident that the ravages of phthisis must entail a very serious financial loss to the community. About 10 years ago, after reading a paper upon Life-table Construction before the Royal Statistical Society, I was met by a criticism, good-humouredly, but at the same time pointedly, made, by a member of the actuarial profession present, that it would be better for a medical man to stick to his stethoscope and not to meddle with matters which properly belong to actuaries. My reply was to the effect that, whatever might be the case with medical men as practitioners, it was certainly open to a medical officer of health to utilise such little mathematical knowledge as he might possess in demonstrating the relations between lives and deaths. Should he, as only too probably he may, come short of the mathematical skill of the actuary he may gratefully accept such correction as the latter may be able to give. But when it comes to translating years of life into pecuniary value the writer gladly concedes that this is the special work of the actuary and one for the dealing with which the community owes to him a debt of gratitude. Therefore I can make no attempt to measure the financial loss due to phthisis or the possible gain by abolishing or considerably mitigating the effect of this disease. I would simply desire to represent to those concerned with the management of the industrial and other life assurance societies that it might be not merely an act of benevolence and charity, but one of self-interest and profit, to subscribe something towards the establishment and maintenance of sanatoria for the treatment of phthisis, so as to aid in the restoration to health and the prolongation of life of those who are stricken with this disease and at the same time to be limiting the diffusion of the infective germs to others. This course would not be without precedent for such exists and is already given in Germany. It is only the adoption of a similar principle to that long ago acted upon in their own self-interest by companies insuring against loss by fire—viz., either to maintain fire brigades of their own or to subscribe largely to those established by municipal enterprise.

ON THE PHYSIOLOGICAL CURE OF THE MORPHIA HABIT.

BY W. OSCAR JENNINGS, M.D. PARIS, M.R.C.S. ENG.

IN 1890 I published a little book on the cure of the morphia habit, giving an account of different means of treatment, based upon my researches concerning the craving that had enabled me to wean a considerable number of *habitués* from their addiction, with a minimum of distress and suffering. It may seem an invidious thing to say, but I have no hesitation in declaring that before this there existed no treatment of the morphia craving founded upon therapeutic indications. There was, in fact, no treatment of the craving at all, which is tantamount to saying that there was no systematic treatment of the morphia habit.[1] The so-called "methods" described by contemporary writers consisted of suppressing the morphia suddenly, slowly, or semi-brusquely, and those who could be persuaded to give up their liberty, when they did not die suddenly or commit suicide, were sometimes cured temporarily after indescribable sufferings,[2] but the same ignorance, or rather indifference, concerning the means of alleviating the craving, extended to the means of preventing the discomforts that are liable to occur to those who are left to their own devices after the suppression, and in nine cases out of ten the temporary suppression was followed by a speedy relapse.

I would say at once—for I have long ceased to make any secret of the matter—that my first observations were made in my own case. I endeavoured to analyse and to dissociate the different factors of the miserable wretchedness known as the morphia craving, and I was able to satisfy myself that they were always intensified by a certain number of errors and imprudences that the morphine

---

[1] I except that of Dr. Mattison of Brooklyn, who treats his patients by bromides, codeine, and cannabis indica.

[2] A physician, quoted by Dr. Mattison, expresses himself as follows: "Let him (the patient) quit it short, absolute, and entirely. If he have the will power, trust him; if he cheats, lock him up; put a Hercules over him as a nurse." As it *is absolutely certain that* no one whose addiction is of sufficient standing to warrant the expression "morphia *habitué*" could leave it off suddenly by an effort of the will the Herculean nurse would become a necessity. Here is a picture of the treatment by the same authority. "All substitutes are simply a prolongation of the agony he must go through. ...... The patient who quits morphia, after a long-established habit, suffers from insomnia, diarrhœa, nausea, vomiting, achings all over, and debility to such a degree that it is a marvel how he lives. ...... All this suffering will last from five to ten days. No medicine will do any good, the stomach rejects everything, even a mouthful of cold water. ...... At last, after several centuries of torture, little by little, and without medicine or substitutes, *nature accomplishes the cure.* This terrible treatment, I am sure, is not only the best, but the only safe one to cure, and secure the patient from relapse."

habitué always commits, and that on the other hand, they could be prevented in a remarkable degree by simple dietetic and hygienic observances and remedied by a number of means of treatment that result clearly from unmistakeable therapeutic indications. During the last ten years I have had the opportunity of verifying my first observations and I can now affirm that when the line of conduct which I indicate is followed intelligently, the craving can often be entirely prevented, and in every case attenuated to such an extent that there should be no difficulty about suppression for anyone who is really desirous of giving up the addiction.

It might be supposed that the mere fact of a person consenting to commence treatment would be *primâ facie* evidence of a real desire to be cured and that when the reduction is prematurely stopped it is good proof of the failure of the treatment. This is, however, a false conclusion for there are a great many patients who commence treatment under pressure from relatives or in alarm at certain menacing symptoms and when, as is nearly always the case, a slight reduction has led to a disappearance of these symptoms or when the restraint to which they are necessarily subjected begins to become irksome the first resolutions or rather good intentions are thrown to the wind and the patient resumes his liberty of action. He has not given up the treatment *because of any suffering or even discomfort* but because it has turned out that he has not sufficient unity of purpose to carry out what he was momentarily persuaded or frightened into undertaking.

Besides these two classes of patients—those who would get well if the craving could be moderated sufficiently or entirely, and those who do not intend to do so—there is an intermediate class, those who do want to get well and who have no real craving that prevents but who suffer from an hysterical neuromimetic craving. As is the case in all painful hysterical manifestations it cannot be affirmed that there is no suffering because there ought to be none and because there is no reason for any. It is in these cases that great tact is necessary and that experience is more especially requisite. Such patients should never know how much morphia they are taking, or what other agents are being administered, and as the symptoms although really distressing are entirely ideal, ideal treatment must be adopted. In the case of one lady as soon as she knew that she had been reduced to a small dose of morphia the most distressing scenes occurred, but after a temporary return to larger doses a reduction was carried on rapidly without her knowledge and she had given up the morphia entirely for three weeks before she had any suspicion that she was near the end.

Supposing however that a patient is sincerely desirous of giving up his addiction he should commence by consenting to renounce all liberty of action whilst under treatment—he should give up his syringe and his solution to a sure friend, a medical man or a tried and reliable attendant. It may seem superfluous to take such precautions with a treatment that claims to do away with all real sufferings but with the morphia *habitué* it is better to guard against temptation or impulse and the best evidence of a will to get cured is the temporary renunciation of all freedom of action. It requires a considerable exercise of will to renounce one's free will and the re-education of the will is one of the best guarantees for the future.

When the morphia is associated with some other addiction the first thing is to suppress the other stimulant whatever it may be. If it is alcohol or cocaine there is no difficulty worth speaking of in so doing—indeed the quantity of morphia taken becomes more satisfying being antidoted as it were in a certain degree by the other stimulants, when they are taken. A medical man in London who consulted me by letter was astonished when I told him that he could give up the cocaine without trouble, having been accustomed to look upon this as the most difficult part of his addiction. He wrote shortly afterwards to say that he had not experienced the slightest difficulty in carrying out my instruction. A gentleman who afterwards came under my care had commenced treatment with a London practitioner at the time when he was taking eight grains of morphia and an immense quantity of whisky besides brandy, four grammes of albumin representing the result of the kidney irritation. The practitioner offered to allow him extra whisky if he would give up the morphia, a plan which would probably have resulted in delirium tremens. Fortunately he recognised his danger and shortly afterwards he came to Paris. All alcoholic stimulants were stopped in ten days and six weeks later there was not a trace of albumin.

As regards the rate of reduction I have always been a partisan of gradual progression but the actual time necessary for the cure of any given case, depends entirely upon the thoroughness with which the craving can be prevented by the means adopted. Starting from the fact that it is possible without any other treatment whatever, to wean a person from the morphia habit without his knowledge by a sufficiently slow progressive reduction it is evident that the slower the reduction the less distressing is likely to be the craving. The plan which I have adopted is to proceed as fast as possible, but *as slowly as necessary to effect a cure without distress*. If there were no other means of relieving the craving the treatment would then resolve itself into a suppression sufficiently gradual for each patient but this is no longer the case, and when the patient is perfectly docile, allowing his mode of life to be so arranged that all increasing causes of the craving are eliminated, the residual craving is reduced to its simplest expression and can be so alleviated by the means which I use that suppression may sometimes be obtained in ten days or a fortnight.

It is desirable first to bring about a change as soon as possible in the mode of administration of the morphia. If this can be effected earlier in the treatment so much the better, but if not there should be a gradual substitution of *rectal for hypodermic injections from the moment the patient* is reduced to two grains by the skin. Two grains would seem to be the vital requirement. Above two grains morphine can be found in the urine; below this amount it seems to be entirely consumed. It is not, as a rule, possible to get below this figure without discomfort and here a subterfuge should be adopted. From this point downwards twice as much should be given by the rectum as is suppressed by the skin. In consequence of this the patient who has commenced these substitutive rectal injections at two grains hypodermically will be taking four grains by the rectum when the hypodermic injections are suppressed. But this is in no sense whatever a relapse. The great point to be accomplished is renunciation of the syringe—to wean the patient from his accustomed *stimulant*.

Hypodermic injections of morphia give energy and "go" and it is for this reason that the syringe is resorted to on the slightest pretext. It is the exact equivalent of brandy nipping. For the person who has been accustomed to hypodermic injections the effect of rectal injections is quite different. There is no sudden or sensible stimulation and recovery of energy but in its place an even sedation. This sedative effect inasmuch as the dose is larger compensates largely for the want of a syringe but as it is not in the same way stimulating it does not give rise afterwards to the same degree of craving. It is moreover an inconvenient thing to inject morphia by the rectum; the patient will do so to prevent suffering from the effects of hypodermic suppression but it is without the fascination which leads to the constant use of the syringe; he is satisfied to content himself with what is really required to prevent discomfort and has ceased to be the subject of morphia intemperance. It is now that the different means of preventing and remedying the craving that would otherwise result from continued decrease of rectal injection must be resorted to.[3]

The want of morphia shows itself by certain symptoms which, as has been said, are natural indications of the treatment required. It should be borne in mind that when giving up morphia it is a question of giving up not an habitual sedative but principally a stimulant and a stimulant of such transcendent power that the vital collapse which results from its suppression far exceeds anything that could result from the privation of any other stimulant.[4] By gradual reduction and change from the more stimulating hypodermic, to the sedative rectal injections, the collapse that would have resulted from sudden hypodermic suppression is avoided, but if there were nothing to be done beyond progressive reduction of the morphia (as is the case outside of my treatment), the final suppression would, unless spread over a long time, still give rise to a great deal of discomfort. Observation shows that the suppression of morphia, which amounts practically to the suppression of a fictitious vital force, gives rise to general functional depression, and in the glandular organs to metabolic perversions, and these disturbances constitute our therapeutic indications.

---

[3] I taper off the morphia as fast as is possible but, as I say elsewhere, as slowly as is necessary *for each case. During the period of* rectal substitution there should be no craving whatever, but when the [illegible] injections are [illegible] and the rectal injections have [illegible] will be proportional to the [illegible] to the means of prevent[illegible] [illegible] this stage in a few days [illegible] and when the last fraction [illegible] render the transition from easy still [illegible] using doses of Duquesnel's [illegible] i.e., a preparation of opium in which the narceine alkaloid is retained after elimination of morphia, codeine, and all the others. This makes the last jump free from the discomfort that there might otherwise have been, for there is very little addiction and no craving that cannot be relieved. After a few days to enable all desire for morphia to disappear it is easily stopped. I have, like many French specialists, also tried at this time an alkaloid derived from aconite known as "napelline." Once or twice it seemed to be useful but further experience has not confirmed what I first hoped from it. It is however harmless and very slightly toxic but it costs 10 francs a gramme and is very difficult to obtain.

The heart always suffers and the sphygmographic tracing shows a sluggishness that is only too eloquent as regards discomfort. This constitutes my first indication of treatment and heart tonics form, then, my first means of preventing the craving.

As is the case with each of the means of treatment that I have proposed, the utility of heart tonics has been endorsed by every subsequent French observer. I shall content myself with one quotation only. Dr. Pichon expresses himself as follows:—

> The pulse of the morphia *habitué* does not afford to the finger any important indication. ...... But there is a registering apparatus, the sphygmograph, which compensates for this insufficiency as regards delicacy of touch and which analyses the slightest arterial anomalies. It is in this manner that the experiments to which we refer and which we had the good fortune of witnessing were made. ...... These researches were made by Dr. W. O. Jennings, attached to the laboratory of Professor Ball, upon the numerous morphia *habitués* who were attending the clinic at the time. ...... Before arriving at a definite result Dr. Jennings took a series of tracings from patients in different stages of morphinism—state of want, state of satisfaction, intermediary condition, and normal condition.

Dr. Pichon then gives the conclusion of the communication presented by Professor Ball and myself at the Academy of Medicine, and he adds: "Nous avons contrôlé à plusieurs reprises ces savantes recherches. Nous avons pris un très grand nombre de tracés et nous sommes arrivés au même résultat." He then points out that the sphygmographic examination of the pulse is, as I have always taught, the best way of telling whether the patient is honest or not in carrying out the prescribed reduction. If the *plateau* is not obtained when the patient ought to be in a state of want there need be no hesitation in concluding that he takes morphia secretly. Dr. Pichon continues:—

> This discovery has been the pivot of the physiological method which appears to have been given (as we shall see at the end of the chapter) very good results. After numerous trials Dr. Jennings found that the sphygmographic tracings, after use of sparteine and trinitrine, gave the same results as morphine. The problem was solved physiologically and clinically. It [the treatment] often gave before us excellent results. ..... Most interesting practical consequences result from these physiological discoveries both as regards diagnosis and treatment.

Further on, after passing in review the different treatments that have been advocated, Dr. Pichon concludes:—

> We should prefer the physiological treatment of Jennings based upon the action of sparteine and trinitrine. ...... We have seen that these two therapeutic agents replace absolutely the circulatory action of the morphinic euphoria, and overcome the state of want by causing the disappearance of the plateau.

Although the administration of heart tonics has been described under my name in some of the monographs as the "physiological method" of treating the habit I have never claimed more from heart tonics than the power of relieving the craving in so far as it is caused by heart sluggishness. This is something—I may even say a good deal—but it is not all, and there are other factors of the craving that are equally important. Before passing to them I would say that in my first memoir I used sparteine because it was easy to demonstrate to the students (when I was attached to the clinique of Sainte Anne) the recovery of the heart, but in my more recent publications I expressed the opinion that it was better to avoid hypodermic injections of any kind in convalescing *habitués*, and that a more even strengthening could be obtained by digitalis given in the usual way. I have recently had occasion to go back to my first opinion. In a case where the digitalis appeared to have lost its efficacy, sparteine did all that was necessary, being even more comforting than I should have expected from a simple cardiac tonic.

The next great factor of the craving is hyperacidity of the stomach and organism generally, and this naturally suggests as a treatment the administration of bicarbonate of soda. For 13 years I have been calling attention to this fact in English publications, and although still apparently unknown in England its importance is now recognised by every writer on the continent, Professor Joffroy of the Paris School of Medicine being the last one to endorse it and to recognise my claims to its authorship. It may seem strange to make a therapeutic agent like bicarbonate of soda play an important part in the treatment of the morphia habit, but some go even farther than this, and make it little less than a panacea. Erlenmeyer has even given this means of treatment the name of "chemical demorphinisation" and he labours under the impression that he was the first in 1895 to suggest its use. As I pointed out in four different publications before that date that hyperacidity is an important factor of the craving and insisted in each instance upon the value of bicarbonate, the only thing that can be claimed truly by Erlenmeyer is to have given a high-sounding name to a discovery of mine and to have correspondingly exaggerated its importance.[5]

It is quite evident that hospital or asylum patients can be forced to give up their morphia whether treated by bicarbonate or not, but bicarbonate will not help to the extent of suppressing the craving by itself, which is the only case in which it would deserve the name of an adequate method. Bicarbonate relieves the craving in so far as it is caused by over-acidity in the same way that heart tonics relieve it *quâ* cardiac sluggishness and nothing more; but it is none the less satisfactory to find that according to others I have understated rather than exaggerated its value.

Various other means of relief may be applied according to symptomatic indications, but the last of my therapeutic triad is the hot-air bath.[6] And here, again, I have certainly not overstated my case, for the author of a Montpellier thesis makes alternate douching with hot and cold water a method by itself, and there is now an institution for the cure of the habit by hot-air baths alone. It is highly probable that other means are used concurrently, for however valuable the hot-air bath may be the cure will never be too easy, and there can be no reason for rejecting any one of the means that have been proved to be useful. In a recent case, wishing to test the value of the baths alone, a very unmanageable patient was submitted to this treatment, but he contrived to cheat and it did not prove nearly as satisfactory as my *confrère*, the exponent of this treatment *and who was directing it, had promised. Being* afterwards placed under conditions which prevented all deception the system of rectal injections, with bicarbonate of soda, was substituted, and he was cured without knowing when he had passed the Rubicon. In alluding to this case I am not desirous of detracting from the value of the hot-air bath inasmuch as here, again, whatever may be the value of the idea, it is my own and forms an integral part of my method of treatment. It is better, however, not to expect from it more than it can do, and in most cases, however great the relief obtainable from the bath, it stands to reason that it cannot be as helpful alone, as the association of the different means of treatment. The effect of the bath, I feel sure, is largely due to its tonic and sedative action, but it may also act as an eliminator of some excitant of craving. This may possibly be the oxi-di-morphine which is formed in the body and is considered by Marmé as its chief cause, experiments having shown that oxi-di-morphine when injected into the system in a virgin subject produces the symptoms of craving. It may be also, as I have always maintained, that it is a moderator of acidity, and this would explain its value in the after-treatment, when the ex-*habitué*, unless extremely abstemious, is saturated with acidity and when it would be difficult to explain the spurious cravings by oxi-di-morphine.

---

[4] Some years ago I treated a patient at Sainte Anne—a girl who walked from Brussels to Paris *through* the snow because she had not the money to pay for the train. During her journey she lived upon what bread she could purchase for two or three sous a day, being entirely kept up by frequent injections of morphia.

[5] In my contribution to the *Encéphale* in 1887 I say: "The only medicines that have always seemed to me useful are bicarbonate of soda and preparations of valerian;" and in a note I asked whether this is due to a neutralising action on the acid products of imperfect combustion, &c. In three or four other places I allude to the possible rôle of acidity in the morphia habit and to the value of bicarbonate of soda also in the after-treatment. In 1890 ("Cure of the Morphia Habit," p. 80) I say: "One of my invariable recommendations when there is any stomach difficulty is the administration of bicarbonate of soda in the form of Vichy water. Its effect in the relief of the craving is often immediate, not being limited to the neutralisation of over-acidity of the stomach. Alkaline solutions increase the efficiency of the heart's action and cause contraction of the capillaries, a result which lessens abdominal stasis and helps to facilitate the general circulation." In the Medical Annual, 1894: "Dr. Haig has pointed out (as I hinted seven years ago) that the condition of the organism as regards acidity is one of the factors of the craving. This accounts for the immediately soothing effect of bicarbonate of soda. ...... During this period the discomforts which are caused by the overcharging of the system with uric acid ...... everything should be done to prevent the formation of acid and to promote its excretion. ...... Bicarbonate of soda should be given according to indication, &c." These quotations show pretty conclusively that Erlenmeyer, who announced his discovery in 1895, has copied from me, perhaps unconsciously, although curiously enough he contributed a paper to the *Encéphale* the same year as myself. The treatment therein described—his so-called rapid method—is the one recommended by the few writers, Clifford Allbutt among others, who were not acquainted with mine. Since then Erlenmeyer himself has solemnly renounced this method (*Progrès Médical*, 1896) for his so-called "chemical demorphinisation," which is in reality part of my treatment.

[6] Until within the last year, I wrote in 1890, I generally used to prescribe some kind of hypnotic at the last critical moment, chloral, methylal, hydrate of amylene, sulphonal, &c., but now I rely mainly on the hot-air bath, repeated, if necessary, and followed by the cold douche. For some time after the termination of the treatment I continue these baths, which are also the best means of preventing and combating any revivescence of the craving, and it was through their action as a preventive of relapse that I was led to use the hot-air bath as a means of treatment. ..... The moderate restlessness which occurs when patients are properly treated, disappears entirely in the hot room of the Turkish bath; and the subsequent massage and cold douche form the most perfect sedative that a morphia patient can be allowed. There is no better means, moreover, of dealing with the revival of the craving that occurs from time to time, especially under the influence of indigestion. (On the Cure of the Morphia Habit. Baillière, Tindall, and Cox, London, 1890.) In several of the cases reported, moreover, its use is especially noted; it is mentioned in one case that for the last week the patient took Turkish baths regularly. As a matter of fact, I used the Turkish baths long before 1890, for in a reprint of my paper in the *Encéphale* in 1887 I stated that it was an "excellent means of calming the agitation caused by attempts at suppression, giving rise to sensations that resemble morphia and being foll [illegible] to the [illegible] which agitated"; and speaking of th [illegible] the paper is founded, I said: [illegible] ic or as [illegible] calmant is felt he has recourse [illegible] uld be [illegible] difficult to find a more efficacious means. In the *Medical* [illegible] *l* (1894) I was even more emphatic as to its value and as to its importance as a regular part of my method.

Such, then, are the main factors of my treatment. But *considering that acidity of the system in general, as well as* hyperacidity of the stomach plays a part in the causation of the craving, I always insist on a moderate and, as a general rule, on a non-alcoholic *régime*. In cases where there is at the same time neurasthenia there may be spells of restlessness and a tendency to movement, but at the same time a disinclination to exertion. Here a hammock or a rocking chair affords the means of combining both movement and repose. The patient must try to woo back sleep, and *for this purpose there must* be no reading in bed during the progressive reduction, a practice by which the effects of the previous night's dose are wasted in keeping him awake and sustaining intellectual activity. For insomnia cerebral galvanisation is sometimes magical, but if unsuccessful the best hypnotic is trional. Fluid extract of coca and sometimes kola are used frequently and the only other drug that is taken constantly by my patients is valerianate of ammonia (as prepared by Pierlot) which was taken for the same reason many years ago by Coleridge.

I would give a warning against the synthetic derivatives of morphia recently devised—dionine and particularly heroin which is largely vaunted now as the treatment of the morphia habit *par excellence*. The craving following its use is infinitely more unmanageable than is that of morphine and in two cases treated by me recently the doses were rapidly increased and the patient became violent when it was attempted to suppress it. It is only second to cocaine as a drug to be avoided.

It has been said and repeated that ex-morphine *habitués* are subject to periodical revivals or tides of craving and that these discomforts are more likely to occur in those who have undergone a slow reduction. Both statements are errors of interpretation. In the ex-*habitué* there is always a most extraordinary return of vitality after suppression, a kind of vital exuberance which is so certain that however grave may be the condition of a patient during his addiction, restored health may be promised if the habit is renounced.

One of the best proofs indeed of the advisability of the progressive plan is the fact that when properly carried out patients generally put on flesh during the treatment, and as soon as the morphia is entirely set aside the increase of weight is hourly visible. I have several times known patients to gain two pounds and even a little more per day. This physical recuperation has been taken as an indication to gorge such patients with food, but although the power of assimilation is good, the nervous equilibrium is unstable and when the patient is overfed it leads to metabolic perversions of different kinds. The ex-*habitué* has acquired more or less completely the congestive habit of body which goes with vital exuberance and nervous instability, and one of the consequences of this is a tendency both to hyperchlorhydria and excess of uric acid, both of which are factors of craving. Besides this the ex-*habitué* is generally polydipsic and boulimic and, being encouraged in the matter, he does not restrain his appetite, drinks as a rule freely of fermented drinks and eats in proportion. As he is easily tired and has a disinclination to active exercise he is nearly always saturated with uric acid and on the imminent verge of bilious or gastric failure. This is the real cause of what are called the "after-cravings," for it is easy to understand that when saturated with acidity generally and perhaps suffering also from acute or chronic acidity of the stomach the symptoms experienced will be those associated in the past with these conditions—that is to say, a feeling of morphia craving. We must also remember that every morbid sensation during the past addiction having been uniformly treated by the injection of morphia every malaise in the future will suggest by association the idea of craving for morphia. The best proof that these are not real cravings is in the result of treatment, for if properly treated the craving will disappear and when the ex-*habitué* is careful to lead an abstemious life he is not liable to any such revival. Besides these remedial measures, the ex-*habitué* should do everything he can to promote a healthy tone of the system, taking as much exercise as possible without undue fatigue, to which end he will find cycling—for preference the tricycle—invaluable. Another prophylactic precaution is the regular use of Turkish baths, and with these means the bogey of returning tidal cravings may be set at defiance.

The following cases represent aptly the different points insisted on in the preceding paper. The first is an example of a "demorphinisation" in which all the different means of treatment recommended were employed methodically, *according to therapeutic indications. The patient* was not only cured without suffering but thanks to the observance of a suitable *régime*, was entirely free from any kind of suffering afterwards.

CASE 1.—A man aged 46 years, commenced the use of morphia 20 years ago for gastralgia and had continued it on account of the relief which it gave to business anxieties and the increase which he experienced of business capacity. Besides which his wife having left him when he was just beginning its use he *had drifted into two irregular liaisons*, and he at first found the morphia invaluable for keeping him up to the mark. From twelve grains which he was taking when he commenced treatment we proceeded by half-grain reductions to eight grains, thence by one-third of a grain to four grains, and from four grains onwards by one-quarter grain reductions till the end of the cure. Towards four grains there was a tendency to acid dyspepsia which was, however, kept in check by bicarbonate. But henceforth he consented to be abstemious in *food and moderate in* wine, and his digestion was much improved. From four grains downwards he took a hot-air bath night and morning. As we neared two grains he was less complimentary than usual concerning the result of the treatment, but on my having to put him on a somewhat slower reduction I heard no more complaints of discomfort. At two grains rectal substitution was commenced and the syringe was given up with the greatest satisfaction. The four grains of rectal morphia were reduced by thirds to three grains, by fourths to two grains, and by fifths till the end, and from two grains onward the hot-air baths, which had been temporarily suspended in the course of the rectal substitution, were resumed. No medicine besides sparteine, bicarbonate, valerianate, and coca were used at any time. On the day following the last centigramme of morphia the patient took three cubic centimetres of Duquesnel's meconarceine solution, two on the following day, and one cubic centimetre on the succeeding night. He left Paris on the day after and in several letters, one as late as seven months afterwards, he assured me that he had never had any discomfort that could be said to amount to craving. Infractions of temperance were surely followed by pseudo-craving, but knowing its cause he very [illegible] them and was always able to remedy them by the means which I have so much insisted upon. The only drug he had taken on leaving me was trional, which he had given up a month afterwards. He fully endorsed my statements as to the value of the Turkish baths and of the use of cycling, but when he had fully recovered his strength he preferred golf. In his last letter he made the remark with which I will close—that with such means of preventing and remedying the discomfort that might otherwise occur any morphia *habitué* who relapses does so because it is his pleasure.

The next patient shall give his own account of his experience.

CASE 2.—The patient was a medical man who had given up the practice of the profession for another career, in which he occupied a most distinguished position. I first heard from him in a letter from Tasmania. He says:—

> Nearly a year ago I read a reprint of your paper on the morphia habit. As a morphia victim of some years' standing, though only 43 years of age and still in excellent health, it opens up a new hope to me. I am convinced that under your treatment I can escape from this frightful bondage. Alone or under the ordinary treatment I know I cannot. I implore you as a matter of common humanity, as a brother physician, to reply to my letter at once. ...... It is life or death to me, my future depends on your reply. For God's sake do not neglect this.

His next letter was from London eight months later and he wrote reminding me of his previous communication. He began by giving some information about himself and he confessed that he had at first written under an assumed name. He had taken morphia for 11 years. In my answer I told him that I was quite willing to undertake his case if he would conform absolutely to my conditions, and I advised him either to go to St. John de Dieu or to place himself as a boarder in a nursing institute which I recommended where he could obtain a comfortable room and could have as his attendant the son of the directress, who had acted in that capacity before for several of my patients and whom I had found to be unusually intelligent and competent. I warned him, however, that his attendant would be in a certain way his keeper and that although he would be free to go about as he liked he would have to submit to constant surveillance. In his reply he expressed himself as follows:—

> I am glad you can accede to the idea of constant personal attendance; but he must be a man I cannot bribe, as I know I cannot hold myself responsible under certain conditions. You need not fear any resentment on my part at any measures you may think essential for treatment. And I can tell you plainly beforehand that when suffering for medicine as I have done a few times in my life when the accidents that one is subjected to in a wild country have cut off my supplies suddenly I think I would commit any crime to obtain relief; and, indeed, I have ridden alone, night and day, through 200 miles of the most dangerous Indian country in the world, to renew my supply. ...... My main fear is that while I may succeed in getting rid of the habit there will be such a constant craving afterwards that in some moment of despair I shall fall back again.

The patient came over to Paris and, as suggested, took a room at the nursing institute with the attendant I had advised. During his treatment he used to get up late in the morning, take a lesson in French, then lunch, after which another lesson on the 'cello. Then he would go to different places of amusement and interest. After dinner he played whist at my house, seldom leaving before midnight. When the morphia was entirely left off, he continued as an act of precaution to reside where he had been living and to retain the services of his attendant. He did not leave Paris until he felt perfectly sure that there was no fear of the after-cravings of which he had expressed so great a dread. Before leaving he sent me the following account of his experience:—

> It being now nearly two months since my cure was completed, I will endeavour to give you a brief *résumé* of my feelings, condition, &c. I have experienced not the slightest desire for morphine since I gave it up, and to my astonishment if it ever enters my mind at all it is as something that in my present condition would only congest and benumb me. So that I do not feel that it would be pleasant even if it were not harmful to take. I shall preserve this illusion as long as possible. My strength is slowly coming back, though much impaired at present by a severe influenza. I expected to suffer much from want of sleep, and the first few nights after my cure did not get an hour's sleep. But as soon as I obtained the galvanic battery that you recommended me and passed a constant current of three milliampères through the brain, for a few minutes on going to bed, I at once became intensely sleepy and the same thing happens nightly ever since. I had no belief in its efficacy in my own case, but it has certainly succeeded, and I have not taken a grain of chloral, bromide, or other hypnotic since. I used to have periodical headaches; since my cure I have had none. The bowels that formerly could only be moved by artificial means are quite regular again. I have lost nearly all the fat that was rather marked in the
> suffered fro e reducing the morphia I
> it. With sl l the years I have taken
> since when until I had given it up,
> have a natural (never loose) movement about every second day. The whole world has taken on a different and brighter aspect to me, and I can only finish by saying that I am firmly convinced that you are the only person that could have assisted me to be cured and, above all, *to have no desire for morphia left* in a reasonable time, and without experiencing any actual suffering or unbearable discomfort.

What follows is from fuller notes sent to me six months later:—

> I began with an ordinary dose of 12 grains a day. For the first two weeks there was absolutely no discomfort. This was whilst reducing to four grains by the skin. A certain *ennui* only due to the substitution of regular habits for the more careless life I led. Sleep and appetite, the latter rather poor for years, remained as usual. Then came two or three days' discomfort, the craving coming on before the morphia was due and causing that restlessness that I believe to be indescribable by a person that has not experienced it.[7] *But, after all, it was only discomfort and could be thrown aside and forgotten temporarily if I could only get absorbed in some interesting occupation,* such as a game of cards or billiards. This was between four grains and three. After this little hitch the reduction proceeded without any serious discomfort, though always a certain *ennui*, until I reached the point where you give up the hypodermic
> s morphine by the rectum. This
> v eatment for me. The long-con-
> t sed dose of morphia much more
> than compensated for the less active effect given. Fairly good nights were obtained by reserving nearly half of the 24 hours' allowance for the evening dose, but a little discomfort during the daytime. As the day's dose diminished down to a few centigrammes, the discomfort became more marked, *but always endurable, as shown by the fact that my condition was never such as to prevent me taking a daily lesson in French and on the violoncello, going to your house, and playing whist afterwards.* Indeed, I attributed much of the ease with which I got through the ordeal to following your advice in regards to keeping myself interested and busied as far as possible even when I had little inclination for it.
>
> The end of the cure was not particularly hard except that for some nights I was troubled with a sleeplessness that was rapidly demoralising me when you fortunately recommended a constant current from a weak battery. I tried it without the slightest hope or belief that it would help me; but the result was instantaneous and constant. It put me to sleep in from 10 to 20 minutes, and during the first few days of lassitude and weakness gave me from five to six hours of good sleep nightly. Later I slept naturally six hours, and since my return home, four and a half months after treatment, I sleep naturally seven or eight hours and never read over 10 minutes on going to bed. In the past three months the only drug I have taken has been two doses of bromide of potash. I had no looseness of bowels during my treatment and since its completion have taken neither medicine nor injection, they being perfectly normal. I have gained 20 pounds in flesh, though not about the abdomen; have my normal appetite of former times, and excepting a decided sensitiveness of the respiratory tracts suppose I am as well and strong as I could ever expected to be at middle age. I do not find that indiscretion in eating or drinking produces any craving for sedatives, however uncomfortable I may feel. This condition of things I owe to you and am happy to acknowledge it. With a somewhat long experience of morphia and its *habitués*, I must express as my firm belief that the only possible way that I have ever heard of by which I could succeed in escaping from the use of the drug as well as from all craving for it was by following the principles you so forcibly and frequently laid down for me—i.e., gradual but voluntary suppression, constant surveillance without restraint, and absolute truthfulness with you as to my position; nor could I have carried these out without your constant encouragement and your insistence that success was plainly and certainly within my reach if I would only keep up the necessary patience and strength of mind to fight off the tedium and feeling of weakness.

I will add only one detail that my patient omits, which is that his virility, which was suspended as is usual in morphine *habitués*, returned in a remarkable degree after suppression.

Those who have experience of the morphia habit will understand how slight the discomfort which was felt by this patient must have been in comparison with what it otherwise would have been. It did not prevent him taking a lesson each day, in French and on the 'cello, and he was able to play whist all the evening. I find, moreover, on reference to his note-book, that the discomfort that did occur coincided with an attempt on his part to hasten the reduction. I do not recollect now (for it is not stated either in my notes or in the patient's report) for what reason he was unable to take the Turkish bath. Satisfactory as was the result it would have been even better had he been able to do so.

The third case is interesting from the fact that the patient was addicted, not to morphia, but to opium, and that the addiction had lasted nearly 20 years. It shows the ease with which a hopeless addiction may be given up if properly treated.

CASE 3.—The patient, a married medical man, commenced the use of opium at Cambridge between 19 and 20 years ago, taking it as a mental stimulant whilst working for the mathematical tripos. For some time the dose did not exceed a few drops; but it gradually increased until from two to three ounces daily were consumed. At different times attempts were made to effect a cure, on one occasion the progressive reduction lasting from May to December and ending in a failure. To quote the patient's own words: "The agony which I suffered during the attempt is only to be understood by those who have gone through it." Since then, although there was a speedy relapse, the doses have been kept within limits, the daily quantum varying between two and four drachms. In the month of April the final treatment may be said to have commenced, the patient substituting for the laudanum the use of crude opium which was taken to the amount of 12 grains a day, this having been decreased to eight and finally to four grains daily. It was found, however, that no further progress could be made, and when there were east winds or cold weather it was necessary even to increase this daily dose. From the time he commenced treatment with me progress was uniformly satisfactory. To say that he was entirely free from discomfort would be an exaggeration, but for the whole duration of the treatment he never failed to eat two hearty meals a day and, thanks to the effect of cerebral galvanism, to sleep well. The bowels were constipated or irregular and occasionally the seat of restless pain, besides which there were headaches, exhaustion, and depression of spirits, symptoms which may be attributed to difficulty of digestion.[*] From the beginning of the treatment in Paris digitalis was given, and great benefit was derived from the use of nitro-glycerine in the form of Burroughs and Wellcome's compound tabloids, which contain also nitrite of amyl and capsicum. The daily ration was being taken in one dose only, the first thing in the morning, and the patient who was waiting for his dose at from 6 to 8 A.M. was frequently able to fall asleep after the nitro-glycerine and so to economise several hours, only taking the opium at 11 or 12 o'clock. Within a month from the commencement of the treatment the patient attended a meeting of the Société Médicale de l'Elysée, where I read a short note of his case, and the treatment seemed to have come to a successful termination. I have not given the daily progression for the reason that there were no incidents of interest to record. From the first day to the last the progression was followed as laid down, and the last dose of opium was taken on the day anticipated. The following day, however, possibly in consequence of a chill taken on going to the meeting of the society in an open carriage, diarrhœa and tenesmus supervened, [illegible] what is worthy of [illegible] symptoms lasted for [illegible] maining in bed three days. He remained with irritability of the bowels until I gave him some bromide of sodium which had the happiest effect in that respect. After he returned home he wrote to me that the appetite and diarrhœa were unsatisfactory, but they are now all that could be expected.

---

[7] I find from my own notes that the reason of this was that the patient had neglected to pay attention to the bowels, which had been obstinately confined for five days.

In the preceding cases little difficulty was met with, and there was in consequence but little discomfort, but in those which follow there wer[illegible]

[illegible] medical officer to a hospital and was unable to give up, even temporarily, his duties. Nothing could have looked less promising, but by constant encouragement he was brought through satisfactorily.

CASE 4.—In his first letter the patient told me that he was addicted both to morphine and cocaine as well as chloral, and he asked me to advise him. I replied that I could give him no aid whatever as long as he took cocaine, which when taken with morphine could be given up without any suffering at once. I gave him to understand that there might be considerable difficulty about resisting the impulsion to take cocaine, but that if that were the case he should at once give up his liberty of action in this matter and place himself under restraint. There was a mental impulsion only, not a physical craving. When he had given up cocaine he was to write again. Nothing could express so accurately the psychology of this case as the patient's own letters, which I copy. The first two refer to the suppression of the cocaine:—

> I can't tell you how grateful I am for your letter received this morning. It is indeed good of you to take [illegible] almost on the point of suicide these h[illegible] was *no* way out of my bondage. I hop[illegible] at least in a week. I have given your [illegible] asked him to act on it, how I wish I c[illegible] such absolute faith in you. As you say [illegible] I have never taken it by the skin. Wh[illegible] I do re chloral and morphine? I n[illegible] mouth. Will you let me know? Please don't forsake me yet, my only hope [illegible] I shall leave the cocai[illegible] morphine and 25 gr[illegible] write soon that I have stopped the cocaine. I can only offer you my most heartfelt thanks. God knows I want to become once more what I was and I feel it is only you that can do it, so please don't drop me. I have such [illegible] me faith because one can see you [illegible]
>
> Thanks to you and my faith in you I have taken my last dose of cocaine and my father has thrown in the fire all the cocaine I had. I believed your words that it was a "mental impulse," although I would not have believed anyone else, and I have found, I must say, little trouble in giving it up. I can't understand it, as all the books I have read speak of it as the cocaine fiend and give one the idea that it is almost impossible to break [illegible] to me now. I have so much faith in you, and you alone. Already I am beginning to feel once more a man. I can only thank you and from my heart ever think of you as my saviour.

I gave him the necessary instructions in reply and his next letter was as follows:—

> I have n[illegible] program[illegible] but I ca[illegible] and two [illegible] to do aw[illegible] First he[illegible] night, had I better take them with the night doses of morphine? [illegible] t do any harm? Fourthly, had I [illegible] local chemist is not, I am afraid, [illegible] much and sometimes too little? [illegible] grains. Please excuse me bothering you so much but you are the only one I [illegible] and even [illegible] physical c[illegible] cocaine? [illegible] after a good meal I [illegible] better take some light [illegible] me up just yet, but I feel very sensitive about troubling you so much. I will try my best to carry out your instructions, it is such a help to receive a letter from you.
>
> P.S.—Does a large dose of morphine produce similar feelings to a want of morphine? I have an idea it says so in your book. May I not read, say for 20 minutes, in bed? The reason I ask is it makes me a little sleepy. I quite understand that longer reading would produce a want of morphia sooner. Have you written any other books on this subject? Although a morphine *habitué*, believe me I tell you the whole truth.

It was two months and a half before I heard from him again, after sending the necessary instructions, which consisted chiefly of a warning against over-eating, and the following was his last letter:—

> I would have written sooner only I thought it as well to wait a little before I report progress. By next Friday I shall have been five weeks since the last dose of morphine. I have not forgotten my promise to write to you. Would you like me to write my experience from the commencement of the practice, or only a few notes on the treatment? I shall be only too glad to do anything you require, as I have to thank you for getting me out of it, so if you would like the whole of my experience please let me know. I am afraid I can't supply details of the treatment as I should wish as I became too bad to keep notes, however, I have notes of the last week.
>
> I have taken as you a[illegible] only a few times as I can't [illegible] speaking now of my experie[illegible] ing off the habit. I do no[illegible] has been, as you warned me, not to exceed at meals. I find if I do that I get an almost intolerable uneasiness, however, that is getting better and I only have it sometimes chiefly in the early morning. I sleep well, six to eight hours. I can now take actual walking exercise, although at first I thought I should never be able to do so.
>
> My chief object in writing you now is to ask what you would like as regards my experience. Please don't think it will be any trouble as I am most anxious to show you my gratitude even in a small way as I can't in any other.
>
> I still have very loose motions not exactly diarrhœa, but still troublesome. I clear out the rectum daily with hot enemata. Do you advise me to go on with this? I also have a great many gumboils. Is that anything to do with the past habit, also occasionally a chilly feeling particularly in the back, often accompanied with attacks of sneezing. I don't feel quite ready for work as I wish to avoid all [illegible] till I get [illegible] a little to [illegible] and again [illegible] all never forget.

This case shows most plainly the rôle of plethora and hyperacidity. It checked his progress when he was at four grains, and I gave him to understand then that he could only succeed finally by adding abstemiousness to the other means indicated. After his last letter I again told him that his too excellent appetite was the cause of the tiredness and other discomforts and of "the certain kind of craving" to which he referred.

The difficulties in the next case consisted of the extreme duration of the addiction, the invincible [illegible] and the shattered state of the health which was as unsatisfactory as possible.

CASE 5.—The patient, who was a high official in one of the Central American Republics, began the use of opium 23 years before for supraorbital neuralgia, it having been given him by a New York specialist who guaranteed that he would cure him for $100. The bargain having been accepted he gave him a tablespoonful of the mixture which took away the pains as if by magic. "J'ai cru," said the patient, "que c'était un spécialiste admirable." He found, however, that he was obliged to increase his dose, and drifted into the habit until three years later, when he was taking 24 grains a day. At this juncture an attempt at suppression was made, and as a result five grains of morphia were substituted. Ten years ago the daily dose was 24 grains of morphia, when an attack of pneumonia occurred during which it was reduced to 12 grains, at which it remained. Continuing to enjoy good health, he did not make any further attempt at giving it up, but at length symptoms of dyspnœa set in with stomach troubles that made matters less pleasant. Sleep at night had now become a thing of the past. It was impossible for the patient to repose in bed, and he sat up in his arm-chair reading all night. In the daytime he dosed in the intervals of his receptions. He did not lose his mental vigour or memory. Finally, however, the gastralgia became chronic and his legs began to swell. When I saw him the swelling had disappeared; but in other respects he was the same as he had been for the last three years. The insomnia was absolute at night; the little sleep he had consisted of intermittent dozes in the intervals of receptions. There were also the dyspnœa, which caused him to pass the night in his arm-chair as already related, and painful dyspepsia which made everything but coffee and milk difficult to take. There were great emaciation, his weight being 57 kilogrammes, and extreme exhaustion. Besides this he suffered from occasional attacks of malarial fever. He was to have placed himself under my treatment at once, having left Central America for that purpose only, but being seized with an attack of fever he was induced by his friends to call in an eminent professor of the Paris Faculty, who declared that reduction of morphia in such a state of emaciation would mean death but that when a certain amount of flesh had been put on and the general health had improved the morphine could be diminished without danger. The patient objected that the emaciation was caused by the morphia and that he ought to pick up flesh by leaving it off, but the threats of death being repeated and it being promised that he should gain a pound a week by the treatment he allowed himself to be persuaded. For seven weeks the patient's health continued to decline and his weight decreased to 55 kilogrammes. Another professor who was now consulted gave it as his opinion that it was a very difficult case and advised hydrotherapy, but the patient did not like the idea and decided to place himself in my hands forthwith. He had increased from 10 to 12 grains of morphia and had lost a corresponding number of kilogrammes of weight during the preceding two months.

---

[*] This case was treated 10 years ago, before my means of treatment were as complete as they are to-day.

On commencing treatment he was taking the 12 grains by the mouth, and in one dose only. This was to be taken at 8 A.M., a third of a grain to be diminished daily. On Nov. 1st he had reduced as per programme to seven and one-third grains and now entered the Maison St. John de Dieu. By the 10th sleep, which had been better since the beginning of the treatment, now came rarely before 4 A.M. On the 12th one and a half grammes of hydrate of amylene, repeated every two hours after 12 P.M., gave six hours' uninterrupted sleep. On the 17th the patient felt wonderfully well and was at two grains. The stomach was better than for years previously, the digestion was good, with no craving, and the sleeplessness was remedied by hydrate of amylene. The patient had all the time been taking digitalis and bicarbonate of soda. On the 19th he had morphia, one and two-thirds grains. The patient began to complain of discomfort; and I was most anxious to slow the progression, but his friends (and whenever I called upon him I found him surrounded by half a dozen of them) were all for "firmness." He was therefore constrained to continue at the same rate of reduction. The time for giving the morphia was now changed to 9 P.M. Until the 25th the progression was kept up in the same manner, although extra doses were given when the patient would bear it no longer. Bromide of potassium was now tried, but the next day the patient was miserable, sitting almost in the fire to keep warm. Morphia, one grain. From this date (Nov. 25th) when the patient was taking one grain of morphia, until the 30th, it was decreased by one-sixth of a grain daily, cannabis indica being given in increasing doses from 30 to 70 drops, and laudanum in rectal injections to the amount of 25 drops on the last two days. By Dec. 1st the patient was to have no further medicine of any kind but to rely on the hot-air bath, but he could not bear the feeling of suffocation and the attendant gave him a small dose of chloral. On Dec. 3rd he had slept very little, but he was free from craving. Two days later he left the establishment, still suffering from insomnia, and three months later I heard that with this exception he was doing well, having recovered his health and his ability to sleep, when he could manage it, on a couch.

The most interesting question arising out of this case, in my opinion, is that of the conduct which should be adopted when the patient begins to complain of suffering. I think myself that when a morphine *habitué* has given proofs of firmness and goodwill he should be credited with good faith and encouraged for what he has accomplished, instead of being suspected of a desire to relapse. To put on moral pressure, to make a man do a little more when he has really done his best and has arrived at the limit of endurance, is unwise. Almost the whole secret of treatment in a morphia case consists of knowing when to take the initiative and to counsel slower progress. If the progress has been too fast one may even go back a day or two, but by slowing in proper time all suffering may be obviated and a temporary increase, which is a bad precedent, prevented. It is better for the medical attendant to prescribe the reduction than to be obliged to yield to the patient's requirements.

The next case I report more on account of its intrinsic interest than as an example of a successful conclusion, for though the present condition of the patient was entirely unhoped for I am very much afraid that there is every likelihood of a speedy relapse.

CASE 6.—A gentleman, 30 years of age, wrote to me from England describing his case and asking me to undertake his treatment. Eight years before he had had malarial fever in South Africa with black urine, albuminuria, and general œdema, followed by the most extreme emaciation and prostration, to such an extent that he had to be carried about. For some time he was also annoyed by phthiriasis. Returning to England to die he picked up on the voyage home to a certain extent. But rheumatic arthritis now intervened and the joints became contracted and ankylosed besides being the seat of constant, with periodically increased, pains. The left knee became ankylosed at the right angle. Three years afterwards, consulting Sir William Mac Cormac, this was broken down, the limb being straightened to the position of standing at ease and one of the arms is now fixed at a right angle, the other assuming naturally this angle but having slight motion of flexion and extension. After the breaking down of the knee the patient began the use of morphia, and his life was passed in going from one health resort to another with his nurses. Besides morphia he became addicted to excessive quantities of alcohol and in driving recklessly under this influence he was twice pitched out of his dogcart on to his damaged limbs. The inflammatory condition had been aggravated by gonorrhœa and his health had not been improved by syphilis. Two years ago he suffered from an acute attack of rheumatic fever and was given such doses of salicylate of soda that the heart's action became extremely slow and imperceptible. The patient remained in a state of coma for 10 hours. His medical attendant having given hypodermic injections of atropine for this condition this alkaloid was also used abusively until he took a tubeful of tabloids a day, symptoms of mental derangement being ultimately caused.

The letter in which I was made aware of these facts was so strange and excited that I did not like the look of the case at all and advised that someone should be sent to me who was well acquainted with the patient and could furnish me with the fullest particulars of his case. A few weeks later his mother came to Paris, and her account of his unmanageableness was such that I would not hold out any encouragement, but I consented to treat him without guaranteeing any kind of result. On his way to Paris he was persuaded to put himself into the hands of a "specialist" who told him that the immediate danger was the morphia and that he would allow him even more whisky to enable him to give this up. He had at this time four grammes of albumin per litre. After a short time he came on to Paris. I saw the wreck of what had been a good-looking fellow, a face and body puffed and bloated from alcoholic excess. Besides the symptoms already described, he was suffering from morning sickness, for which brandy was taken as a medicine, whisky being pegged at during the rest of the day, and wine being taken liberally at meals. There were four grammes per

litre of albumin. I declined to discuss the question of morphia until the last drop of alcohol had been renounced, the cessation of the added addiction being in such a case a *sine qua non*. I felt convinced that my connexion with the case would last at the outside but a week, and, indeed for about this time he trifled with the treatment, but at the end of the week I called one day when he was more than usually fuddled and it appears that he felt so ashamed of himself that he took a
sudden re
all stimu
entirely
baths on account
although he had
For a couple of months the progression went on, but when he had got to about half a grain he was taken with a painful subacute attack of his joints, and thinking that the Paris air did not agree with him he left for Ostend to recruit. Instead of being away six weeks, as was intended, from Ostend he returned to Brighton, relapsing as regards morphine but keeping strictly away from alcohol. His face and body had resumed gradually a healthy appearance; he was able to put on clothes that had been too small for years, and his friends all considered the change in his appearance as miraculous. Five months later he began to experience uncomfortable sensations about the heart and once more he returned to Paris. On this occasion the treatment was renewed, and in the course of a couple of months he got down to a few centigrammes of morphine by the rectum. I begged him to stay until he was entirely cured, pointing out how surely he would relapse, but he was no longer afraid of pain as I had found means to suppress that entirely and he felt sure that he would be able to effect the remainder of the reduction by himself. In Brighton he had two returns of the pains and on each occasion he discovered that he had committed infractions of the treatment that had prevented it unawares. On each occasion the pain disappeared as soon as this was rectified. Finding a month later that he had again relapsed he came back once more to Paris, as I hoped until I should allow him to leave. Besides his crippled condition which always made walking difficult, a swelling had developed on one of the flexor tendons of the foot which was painful on pressure, so that he was unable to relieve his restlessness by walking about. He was then taking two grains of morphia by rectal injections. In 10 days these were suppressed without discomfort, but the day after he felt an uncomfortable restlessness and had 20 drops of laudanum. He admitted that he had frequently had similar restlessnesses as a result of his rheumatic condition and enforced immobility so that it could not, according to him, be fairly ascribed to craving. To indulge him I allowed him to have a small dose of heroin, but I found that in the course of a few days he was increasing the dose and he admitted looking for it with greater desire than he had ever experienced before. It caused also great disturbance of sight and a condition of sub-delirium. It was stopped and a small dose of meco-narceine was given instead. But he was not yet destined to be entirely cured for the nurse let him fall out of bed on his worst arm and a few hours afterwards there was considerable local inflammation and swelling, with a temperature of 103° F. Fearing mischief and in view of his restlessness and sleeplessness I gave him half a grain of morphia hypodermically with the result that the next day the temperature was normal and the joint which had been wrapped up in glycerine of *belladonna* was no longer tense and tender. As I would give him no more morphia he had to fall back on the meco-narceine solution, and the next morning I found that he had taken about a grain. For some days this was continued and my patient then declared that he must go back to Brighton on important business, being convinced that he could give up the meco-narceine by himself in the course of 10 days. It should be noted that with the exception of the two occasions above mentioned there had never been the slightest return of pain whereas for years previously he had never been a week at a time without experiencing it, especially in bad weather such as we had been constantly having. Much against my wish the patient left for Brighton promising to write for guidance if in difficulty. For three weeks there was no news and then came a telegram saying that he was dangerously ill and calling for my presence at once. On arriving in Brighton I found that he had relied upon having a sufficient provision of meco-narceine, but that it had run out unexpectedly and it had been impossible to procure any in Brighton. I had felt sure that whatever folly was committed he was safe with the albumin before his eyes from returning to whisky, but this is what he had actually done. He had when I arrived been five days without meco-narceine, steadily drinking whisky, and his heart was in a most unsatisfactory condition. Half a grain of morphia was given to enable the whisky to be stopped immediately. The face was looking bloated and distorted and the urine was slightly albuminous. The next day the meco-narceine was resumed and I stayed for a fortnight until he was taking only three cubic centimetres. A week later he gave me to understand that it was all finished and as far as any real difficulty is concerned there is no reason why this should not be so. The return to alcohol, however, makes me think that there is very little hope of a permanent result, and if one or the other must be taken it is better that it should be a moderate quantity of rectal morphia. In the course of the treatment he had lost over two stones of unhealthy fat.

This case is one of the most remarkable that I have ever met with. The patient was handicapped by his crippled condition which condemned him to immobility and his incapacity to bear hot-air baths. I did not at first expect to meet with any success at all. The case was also remarkable for the excruciatingly painful feelings caused occasionally in the head by certain injections of morphia. Nearly every *habitué* experiences sometimes a painfully constrictive feeling after injections which are supposed to have been thrown straight into the veins, but in this th
speechless and paralysed
his anxiety. In this ca
it probably is—was it
the patient had given up the alcohol and his albumin had disappeared the courage with which he continued the treatment made me hope that he might be weaned without suffering. For although when away from me he relapsed there was no nonsense when he came back and he did not make his discomfort a pretext for delaying progress. Notwithstanding the fact that he was so heavily handicapped in not being able to comply with so many of my recommendations (Turkish baths, amusements, and occupation) I was greatly disappointed that he should feel any discomfort, but instead of grumbling he would seek to console me by assuring me that he had had such discomforts independently of morphia and that although the treatment adopted had put an end to his rheumatic pains the restlessness he experienced was probably due to this cause.

The last three observations are examples of the class of cases to which I have alluded in which reduction of morphia results in hysterical affirmations of discomfort which are in reality false. In such a case it is the knowledge that a small dose is being given that causes the distress which if the progression is properly carried out is purely imaginary. And the patient is not satisfied until he is convinced that he has obtained what he supposes he requires. The psychology of such cases is very complex, but the practical upshot is that these patients should never know how they stand in their progression or what other medicines are being given for their relief.

a cure under difficulties
29 years was sent to me by
before he had had tuberculosis and pneumothorax. He had taken morphia for three years altogether and had been demorphinised five times. Two months previously the morphia had been suddenly cut off, and on leaving the institution where he was treated he had immediately relapsed, declaring to his father that he would always return to the morphia if treated by compulsion, but that he would consent to a gradual reduction on the principles laid down in my book with which he was acquainted. His mother warned me that he could not be believed, that he was the most vicious being in existence, and I afterwards found that he took a positive pride in keeping up his reputation. His body was covered with sores resulting partly from abscesses and having all the appearance of rupia, and the existence of syphilis was proved by other symptoms, amongst them destruction of the nasal septum. He refused to submit to anti-syphilitic treatment in order to prevent the sores from improving and the numerous abscesses [illegible] to continue to have a pretext for keeping up the morphia.

To begin with, the cocaine which he was also taking to the amount of 15 grains was suppressed in a few days. The morphine had been reduced from six grains to a fifth of a grain, and he was beginning to put on flesh. The emaciation had been excessive. My assistant unfortunately allowed himself to be persuaded at this moment to give him a small dose of heroin and in a few days he became quite unmanageable and developed a condition of semi-mania and agitation. When I was told this I stopped the heroin at once, allowing four grains of morphia, and after a fortnight's resistance, rectal injections being substituted and the patient professing to be entirely free from discomfort, the treatment was organised in a much severer manner. He had previously supposed himself to be getting cured voluntarily. After a week it was discovered that he had all the time managed to deceive. Each time the rectal supply of morphine was given he had slipped the cannula off the syringe and fixed it to a hypodermic needle previously inserted in the skin of the abdomen. When this was discovered the possibility of its repetition was guarded against, and the treatment was henceforth carried on without reference to his wishes or recriminations. In 10 days more the morphia was suppressed without his knowing it. He acknowledged that he had had no feeling of craving, but notwithstanding this he felt an irresistible impulse to take any drug that might be left at his hand. A fortnight after the last morphia he recognised that the mercurial treatment which he had been persuaded at last to adopt had been of the greatest benefit. All his sores and abscesses were cleaning and healing; but here, again, to make up for lost time he would treat himself in his own way by excessive doses. He declared that the protoiodide of mercury gave him feelings of euphoria.

The patient in this case is certain to relapse, for although he admits that he has no craving his one wish is to find a pretext for returning to morphia. He is in the same state of mind as the greater number of those who have been cured by compulsion in special houses, and is an example of the hopelessness of a cure being permanent when so conducted.[9]

CASE 8.—An American lady, 28 years of age, voluntarily submitted to be treated in order to please her protector; but when the morphine was getting low, although she did not ask for more, she manifested every hysterical symptom imaginable calculated to force my hand. It began by hysterical vomiting and anorexia. This condition not having been considered by me as a sufficient reason for moderating the treatment, a consultation was asked for with Professor Raymond who endorsed my statement that it should be continued as before. As the progression continued the intention of returning to morphia was admitted, the bitterest complaints were made as to craving, and symptoms of extreme hysterical agitation developed. Fortunately, all her servants recognised that it was their interest to prevent her relapsing and combined to coöperate in the treatment; and the different medical men whom she insisted on seeing, with one exception, declared that the treatment should be carried through. To counteract this rather strange exception I fortified myself by the coöperation of Professor Labadie-Lagrave and henceforth no further interference was allowed and the progression was continued mercilessly. It is not that there was any real suffering, but a refusal to give a supplement of morphia to relieve the terrible craving that was simulated would throw my patient into the most violent excitement. On one occasion, in her anger at not being able to have her own way, she very nearly managed to drown herself in a large American bath. After being received with speechless indignation when it was not with tearful reproaches, I could always manage to excite her interest, and 10 minutes later she would be gaily talking about some absorbing matter, toilette, jewellery, or the races, or, perhaps, the progress of my other morphia cases, in which she took great interest. She recommended to me, for them, "the greatest firmness." The complaints of "craving" would be repeated at first from time to time; but after she had forgotten them two hours would often elapse without its being remembered. The reduction was carried out under these conditions, imaginary extra doses being sometimes accorded, and the morphia was given up as per programme. Unlike the next case to be related, when she recognised that she was cured she was most grateful.

CASE 9.—A lady, aged 50 years, but looking 70 years of age, was sent to me by Dr. Bérillon. She was covered with abscesses, she had scarcely a tooth left in her head, the urine was slightly albuminous, and she was in so great a state of prostration that her ordinary medical attendant in the suburbs did not expect her to live and looked upon her removal to Paris as most dangerous. Before coming under my care the morphia had been kept within bounds to a certain extent by her medical man and she was then only taking 12 grains. In this case the same thing occurred exactly as in the previous one. When the last hypodermic syringes were reached the patient, who was resolved to compel me to return to larger doses, manifested all kinds of hysterical symptoms and claimed to be suffering from the most acute craving. She had begged me on her knees not to delay the commencement of her treatment at first, when alarmed about her condition, for there had been some question of a delay for a few days. But as occurs in these hysterical cases when the morphia was reduced to the period of rectal injections, in which period it is impossible to feel craving, she became loath to give up the syringe and wanted, as a fact, not to renounce all treatment, but to order the progression herself with me to countersign it. She had already been treated by dozens of other medical men who had been compelled either to look on or to throw up the case and she did not intend to allow herself to be constrained by me any longer than it suited her inclination. Supported, however, by her husband, she really took what had been arranged, thinking all the time that she was working her own sweet will. She had been having no morphine whatever for three weeks before she had any idea that she was near the end. Here the strange perversity of the hysterical temperament was fully shown. For tired at last of carrying on a comedy of a scene each night before I would allow myself to give the (imaginary) extra morphine, I informed her one evening that she had taken none for three weeks and that I would not lend myself to this nonsense any longer. Instead of being pleased she became simply enraged, and, having recovered her health, persuaded her husband to give me my *congé*. A few days later she was again taking large doses of morphia, and six weeks after she was found dead in her bed from an overdose of chloral.

There are two interesting points in this case: the first is that notwithstanding her protests of craving when she was aware of what she was taking, she was cured by my plan without discomfort; the second is the fact that in the morphia habit, however bad the physical condition may be, recovery is possible if the morphine is given up.

Paris.

---

[9] My previsions have been realised since writing this paper, the patient having relapsed to cocaine, not morphine—that is, not on account of a craving, but in order to re-taste the regretted stimulation.

PASTEURISATION OF INFECTED MILK.

BY E. SYDNEY ST. B. SLADEN, M.D. CANTAB.,

JOHN LUCAS WALKER STUDENT.

THE danger of using milk containing micro-organisms that cause scarlet fever, typhoid fever, diphtheria, and consumption is diminished by heating it to 80° C., and keeping it at that temperature for 10 minutes. If the milk be heated to 85° C. all such danger appears to be removed. In order to obtain exact information on this point I have collected the statistics contained in the following table in which are given the temperature and time required to bring about the death of, or to inhibit the action of, the tubercle bacillus. This temperature of 85° C. is higher than is required to kill the micro-organisms of scarlet fever, typhoid fever, and diphtheria.

The first column gives temperatures rising by five degrees from 50° to 90° C. The second, third, fourth, and fifth columns give a summary of the results arrived at by G. Sims Woodhead[1] in his report to the Royal Commission on Tuberculosis. The sixth column gives the opinions of various workers on this point.

The danger of using milk yielded by cows that have not passed the tuberculin test is without doubt a real danger, especially in the case of infants, young children, delicate people, and all those who have to be fed on a milk diet.

The danger of using milk that is not heated in any way is sometimes present where the water for washing the milk-cans is contaminated with the typhoid bacillus, or where the milk is infected by the persons employed in the dairies who may be suffering or recovering from mild attacks of scarlet fever or diphtheria. With regard to the above well-authenticated outbreaks have occurred The following evidence is conclusive as to the danger of using raw milk containing virulent tubercle bacilli Dr Harold Scurfield[2] quotes Bang as follows "In any large herd in which tuberculosis is rife one will be certain to find one cow the milk of which contains tubercle bacilli and which has tuberculosis of the udder" Out of 144 samples of milk coming from the Liverpool cowsheds, four, or 2 8 per cent, were found to contain the tubercle bacillus, but of 24 samples of milk "from the country" taken at the Liverpool railway stations, seven, or 29 per cent, were found to contain this bacillus In some later experiments in Liverpool 12 out of 228 samples of town milk—i e, 5 2 per cent—were found to contain the bacillus and nine out of 67 samples of country milk—i e, 13 4 per cent In Manchester 17 out of 93 samples of country milk were found to contain the tubercle bacillus By permission of the farmers the city veterinary officer visited 16 farms from which the milk came, and on 14 of these farms he found at least one cow with tuberculosis of the udder Another example is cited by Nocard[3] The seventeen-year old daughter of a medical practitioner in Geneva was in perfect health up to the end of 1892. No case of tuberculosis had occurred either on the father's or the mother's side of the family for several generations In 1893 she began to waste away and the practitioner was able to assign no cause for the wasting, she died in a few months A post-mortem examination showed that tuberculosis of the bowels was the cause of death Inquiry showed that the family used to spend every Sunday at a small estate on the hills, and that this young girl was particularly fond of milk fresh from the cow Four of the five cows on the estate when tested with tuberculin were found to react and were slaughtered Two of the four had tuberculous disease of the udder Dr R. G Freeman[4] writes as follows: "It has been thought that a protection may be provided by a germicidal action of the gastric juice on the tubercle bacilli That such protection is not afforded by the gastric juice of guinea pigs has been shown by the experiments of Baumgarten[5] and of Fischer,[6] nor by artificially prepared gastric juice by those of Falk[7] As a matter of fact we know that primary intestinal tuberculosis does occur in man Woodhead[8] states that he has seen a very large number of cases in which infection seemed to be from the intestine. Cohnheim, Aufrecht, and Peterson[9] hold the same view Three cases of evident primary tuberculosis of the intestine have been reported recently, one in an adult by Dr Hodenpyl,[10] and cases in infants by Dr Northrup[11] and by Dr J Lewis Smith and the writer[12]

CLINICAL EVIDENCE OF THE TRANSMISSION OF TUBERCULOSIS BY MILK.

Clinical evidence of the transmission of tuberculosis by milk is less satisfactory than is that furnished by some other diseases on account of the long duration of the incubation period, the less acute character of this disease, and the varying degree of susceptibility to it found in different individuals Some cases, however, are reported in which the evidence against the milk is fairly strong Thus, in a dairy in Scotland[13] three cows were found to have tuberculous disease of the udder In the institution to which this milk was supplied the mortality from tuberculosis during the last year was 30 per cent and during the preceding year 40 per cent of the total mortality. Brouardel[14] reported that in a boarding school in which there were 14 girls five contracted tuberculosis from drinking the milk of a tuberculous cow Ollivier[15] tells of another boarding school in which milk from a tuberculous cow was used and in which 13 cases of tuberculosis occurred [illegible] the Children's Hospital at Berne [illegible] in intestinal [illegible] fed upon [illegible] ithack and Sladen[17] found on examination of the Cambridge milk supply that more than half the supplies tested—nine out of 16—proved infective while of the 90 guinea pigs inoculated in the course of the experiments no less than 23 (25 55 per cent) developed tuberculosis There is an opinion prevalent in some quarters that the conveyance of tuberculosis by cream is slight as compared with danger of its conveyance in milk These experiments point in exactly the opposite direction. Three times out of the nine cases in which a positive result was obtained did the cream produce tuberculosis when the sediment failed to do so, and in no single case was the sediment infective when the cream was not equally or more so

The following facts are taken from Professor Woodhead's paper on "Tabes Mesenterica and Pulmonary Tuberculosis":—

> In 14 out of 100 cases in which the mesenteric glands were affected there was no tubercle found in any other part of the body. In the class from which the patients in the Royal Hospital for Sick Children are drawn the infants during the first year of their life, and sometimes for a longer period, are suckled at the breast. After this, however, the diet is extremely mixed, and as a rule it is extremely unsuitable, but it is in by far the larger proportion of cases partially composed of cow's milk. As we have already seen it is after this first year that there is such a rapid rise in the number of cases in which the mesenteric glands are affected. During the first year, whilst the child is suckled by its mother, it is not nearly so liable to mesenteric tubercle as at a later period. Anyone who has worked at the subject will have been struck by the fact that although tuberculosis in the human subj[illegible] et with in young married women, tubercular [illegible] rare—so rare, in fact, that Dr. D. Hubermaas [illegible] nd record only some eight cases. In cattle, on the other hand, where the mammary gland carries on its functions under conditions which are far from normal, this tubercular mammitis is not by any means of infrequent occurrence. Albert[19] has recorded the case of a litter of young pigs, the whole of which, fed on the rejected milk from a tuberculous cow, succumbed to tuberculosis. Numerous other observers—Klebs,[20] Bollinger,[21] Stein,[22] Johne,[23] Martin,[24] Bang,[25] Toussaint,[26] and many others besides Koch,[27] concur in stating that *if milk from cattle with tubercular udders be given for any lengthened period by the mouth (or injected into the peritoneal cavity) tuberculosis will be developed in calves, hens, &c.* ...... *Everyone* engaged in practice will readily recall the numerous cases in which tubercular disease of bone, of synovial membranes, &c., has followed on measles, scarlatina, small-pox, and similar conditions, or in which an attack of typhoid or intestinal mischief or some form had been looked upon as marking the date soon after which serious tubercular mischief was developed. ...... It is of course impossible to bring direct experimental proof to bear in the case of the human subject, but the indirect evidence recently adduced by various continental and home observers, and the examination of series of cases such as those I have brought forward, should be very strong evidence that in children, especially in those who are subject to the wretched hygienic conditions and bad feeding to which unfortunately so many of our poorer class children are exposed, *tuberculosis may be contracted as the result of the ingestion of milk from tuberculous udders.*

It has been shown above in Professor Woodhead's paper that "Everyone engaged in practice will readily recall the numerous cases in which tubercular disease of bone, of synovial membranes, &c., have followed on measles, scarlatina, small-pox, and similar conditions, or in which an attack of typhoid or intestinal mischief of some form had been looked upon as marking the date soon after which serious tubercular mischief was developed." It is precisely in these cases that a liquid but nourishing diet is required. Milk is at once the most suitable food, and it is prescribed and its use enforced for several weeks or may be months at a time. If, however, this milk be given in the raw state (unless it comes from cows certified to be free from tuberculosis) it is more than probable that at times or continuously it may contain virulent living tubercle bacilli. It does not, then, seem at all extraordinary that some of these patients after being thus infected may succumb to intestinal tuberculosis or to *tuberculosis commencing in the intestines*, but having become generalised is more manifest in the meninges or the lungs. Thus, in the extract mentioned above, out of the 127 cases in 100 instances the mesenteric glands were affected, and out of these 100 cases only 20 were diagnosed as abdominal tubercle, and this would be considerably reduced were the doubtful diagnoses eliminated. It should be remembered that all who drink tuberculous milk are not susceptible to the disease, and that even some of the infected may recover. The disease in the abdominal, mesenteric, and other glands may become stationary, and the nodules may calcify, just as the disease or nodules do in other parts of the body.

In Denmark whenever an owner of cattle requests that his cattle should be tested with tuberculin without charge to himself, the State demands that certain rules must be conformed to; amongst the more important of these are the following: 1. After the test has been applied the herd is separated into two portions, the sound and the reacting animals; the milk from the reacting animals must not be used as food by man or animals unless it has been boiled or heated to 85° C. 2. In large dairies, if any of the milk is not used during the day, this milk must be heated to 85° C. previously to its return to the farms where it may be used for the purpose of feeding animals. 3. On some farms it was found that although there was no tuberculosis amongst the cattle a number of pigs contracted tuberculosis and died from this disease. This led to an investigation when it was found that the heating of the milk returned from the larger dairies was not properly done, and that living virulent tubercle bacilli were found in the returned milk. The law now compels all dairies that return unconsumed milk to heat it to 85° C.

Professor Bang[28] states that by a short heating at 85° C. the tubercle bacilli are killed, and if immediately afterwards the milk be well and rapidly cooled it loses its cooked taste; establishments which are carrying out this process of "Pasteurisation" are doing a good business in Copenhagen and other large towns. Calves and pigs, when fed on milk, whey, and buttermilk containing living tubercle bacilli, are exposed to the danger of contracting consumption just as is the human subject. Experiments carried out in Denmark, Germany, and other countries, prove conclusively that this source of infection plays an important part in the dissemination of tuberculosis. Fortunately it has been proved that an excellent butter can be made with cream that has been heated to 85° C. For some years it has been the custom in Denmark to heat cream to 80° C. and more rarely to 85° C. before churning. The new law does not absolutely demand this, but we may consider that the law which demands that all buttermilk must be heated to 85° C. before being returned will as a consequence bring about the practice that almost all the cream will be heated to this temperature, thus removing the difficulty of having to heat the buttermilk separately after churning. In an address given on the occasion of a visit of Suffolk farmers to Copenhagen in June Professor Bang said that in an experiment on five calves that were free from tuberculosis he gave to each of them a feeding of 40 cubic centimetres of milk taken from a tuberculous udder, and repeated this a week later. On post-mortem examination made some time afterwards he found that all five were affected with tuberculosis, the starting point in each case being the intestine. He emphasised this point to show the great importance of maintaining the careful separation of the healthy milk and the tubercle-infected milk so that there may never be a single chance of the milk containing living tubercle bacilli being given to healthy calves.

SURREY CONVALESCENT HOME.—Founder's Day at the Convalescent Home for Surrey Men at Seaford was celebrated on July 27th by a luncheon at the Esplanade Hotel, followed by a reception at the Home. Sir Trevor Lawrence, Bart, the chairman of the committee, said that the income for the year under review was £200 less than might have been expected. The committee submitted their ninth annual report which showed that 622 patients were admitted to the Home during the year from April 1st, 1900, to March 31st, 1901. The statement of accounts showed that the total income was £1657 and the total expenditure £1792.

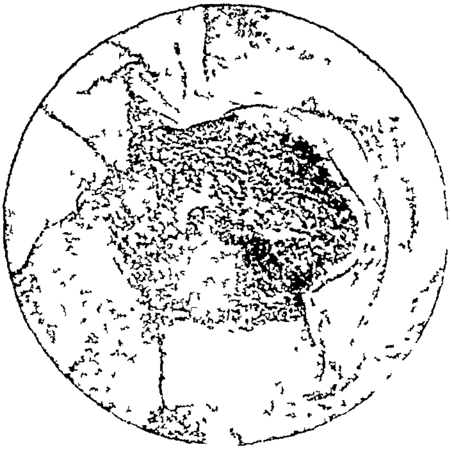
THE ELECTROLYTIC TRANSMISSION OF SULPHUR FROM THE HARROGATE SULPHUR WATER THROUGH A PIG'S SKIN, AND ITS THERAPEUTIC VALUE ON THE HUMAN SUBJECT UNDER SIMILAR CIRCUMSTANCES IN ECZEMA, GOUT, &c

BY FRANCIS WILLIAM SMITH, M D ABERD

IN a paper by me published in the *British Medical Journal* of Feb 16th 1901 I proved that patients could be covered with nascent sulphur in a bath of Harrogate sulphur water by passing a constant current of electricity through it. This was confirmed by Professor Smithells F R S (Professor of Chemistry in the Yorkshire College Leeds) I also stated that treatment of cases of eczema, gout, rheumatism and peripheral neuritis did better by this method than by the patients simply lying in the bath of Harrogate sulphur water for so many minutes I likewise said that I "believe nascent sulphur was driven through the patient s skin into the circulation." I have now proved that it must be so Mr Mark Woodhouse the assistant electrical bathman at the Royal Baths Harrogate, had been able to drive sulphur through three folds of blotting paper by electricity It suggested itself to my mind to try to do the same through a pig s skin

A piece of pig s skin was tied round the mouth of an open mouthed vessel the bottom of which had been previously knocked out A piece of blotting paper was placed outside the skin external to the vessel and the positive end of an anode was placed on the blotting paper The vessel was then filled from the bottom with Harrogate sulphur water and the negative anode was put into it Three milliampères from a 13-celled battery (constant current) were turned on for half an hour The result was that nascent sulphur was deposited on the pig s skin driven right through it, and on to the blotting paper at the positive pole

FIG 1.

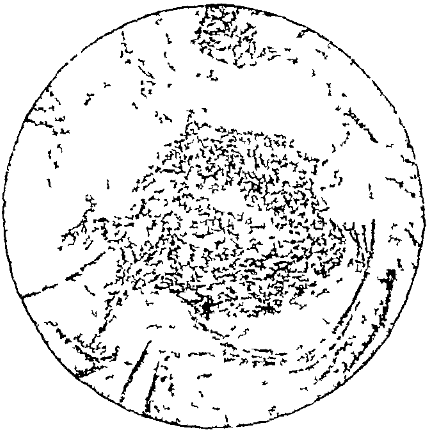


Sulphur deposited on a pig s skin by electricity from the Harrogate sulphur water

The three illustrations demonstrate what I mean They are reproduced from photographs taken the next day when the pig s skin was dry The first two (Fig 1 and Fig 2) lost their round shape as tied round the neck of the vessel This is from the puckering of the skin in drying The reproduction on the blotting paper (*Fig 3*) shows the exact size and shape because the blotting paper did not alter in drying

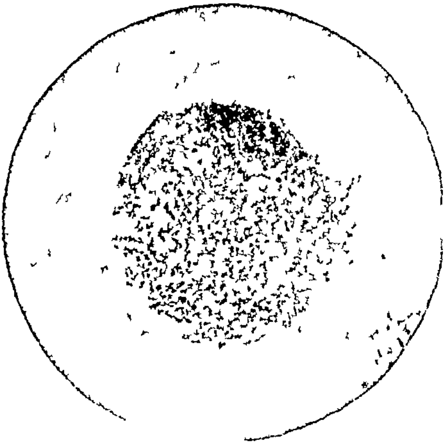
And now as to the therapeutic value of this discovery on the human being whose body *is subjected to the same* electrical treatment in the same kind of sulphur water bath with the constant current I consider that patients suffering from eczema do much better by treatment by this method than by simply lying in the sulphur bath During the last two months I have had good proof of this as the patients themselves and the attendants at the Royal Baths know I will not occupy valuable space with cases but such are the facts Many cases of long standing which had derived no benefit by the old simple sulphur bath yielded to treatment

FIG 2



Sulphur driven through a pig s skin by electricity from the Harrogate sulphur water

FIG 3



Sulphur driven on to a piece of blotting paper having been driven through a pig s skin by electricity

Of course driving sulphur through a dead skin must be a very different thing from sending it through a living one where all the vessels and nerves are alive and active I hope therefore that this simple discovery may be of benefit to those who suffer from eczema (especially gouty eczema) gout rheumatism and peripheral neuritis

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

CURIOUS SYMPTOMS AFTER ADMINISTRATION OF NITROUS OXIDE FOR DENTAL EXTRACTION.

By A. STANLEY GREEN, M.B., B.S. LOND.

ON July 26th, 1901, I administered gas for Mr. T. H. White to a man, aged 26 years, using Barth's inhaler and allowing plenty of air. No trouble was experienced in producing complete anæsthesia and four teeth were extracted. A few minutes after recovering consciousness the patient complained of a numb feeling occurring first in his hands and then in his legs and feet. His hands were pronated, the fingers being slightly flexed and the thumbs strongly adducted. His hands were vigorously rubbed, but he complained of great pain. His respirations became rapid, at first sighing in character and then accompanied by stridor. His pulse was 84 and his colour was excellent; he was very restless and was quite unable to keep still for a moment. He was placed in the prone position, but he begged to be allowed to sit up. He was quite unable to articulate. As the symptoms continued for more than 20 minutes I compelled him to lie down and the pain gradually subsided, and after an hour's rest he was sufficiently recovered to return home. I know the patient well and he is not by any means of a hysterical temperament. I have administered gas more than 1000 times during the past three years and have never met with such a case. I should like to hear if any of the readers of THE LANCET have met with a similar experience.

Lincoln.

PISTOL-SHOT WOUND OF THE ABDOMEN.

By COURTNEY NEDWILL, M.D.R.U.I., M.R.C.S. ENG.

THE patient was a boy, aged 10 years, who was admitted into Christchurch Hospital, New Zealand, on March 18th, 1900, under my care Dr. A. J. Orchard of Christchurch, who was the first to see him, ordered his removal to the hospital. Dr. Orchard also very kindly assisted me at the operation. On admission the boy vomited bloody matter and was suffering from shock. He had had a full meal a short time before the accident. A small perforating wound of the abdomen in the middle line and about two and a half inches below the umbilicus had protruding through it a piece of soiled omentum three inches long. The skin having been purified the abdomen was opened in the middle line and the protruding omentum was ligatured and cut off. Nine perforations of the bowel, most of them considerably ecchymosed and contused, were brought together by Lembert's sutures. The perforations on the side of entrance were easily brought together, but on the side of exit they required to have the mucous membrane pushed back. Out of one of these openings a solid plug of fæces protruded. Two additional wounds of the mesentery were closed by sutures. For a couple of days the boy complained of pain and had a temperature just under 100° F., but afterwards the history was uneventful. The bullet was not discovered and the patient was discharged in three weeks.

In THE LANCET of Feb. 3rd, 1900, p. 310, Mr. A. Pearce Gould reported a successful case in which there were four perforations of the small intestine. I am induced to record this case on account of the number of perforations, but in view of recent South African experiences I am not prepared to say that the boy would have died had I contented myself with removing the soiled omentum and not opened the abdomen, although I fear the excrement extruded from the gut would have produced bad results.

Christchurch, New Zealand.

A Mirror OF HOSPITAL PRACTICE, BRITISH AND FOREIGN.

> Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv., Proœmium.

SALFORD ROYAL HOSPITAL.

A CASE OF SIMULATED APPENDICITIS AND A FATAL CASE OF RECURRENT HÆMORRHAGE FROM THE EAR.

(Under the care of Mr. HERBERT LUND.)

THE contracted condition of the ascending colon in Case 1 was in all probability due to scarring after ulceration occuring during the attack of typhoid fever, though it is rare indeed for typhoid ulceration in the large intestine to be sufficiently extensive to give rise on healing to any noticeable diminution in the lumen of the colon. In such a case as this lateral anastomosis between the lower end of the ileum and the transverse colon might be of benefit. Case 2 is a very striking illustration of the importance of treating early all septic affections of the ear, even of the external auditory meatus. It is doubtful if the fall had anything to do with the subsequent suppuration.

CASE 1. *Contraction of the ascending colon giving rise to symptoms simulating recurrent attacks of appendicitis.*—A man, aged 24 years, was admitted into the Salford Royal Hospital on Sept. 6th, 1900, suffering from repeated attacks of pain chiefly confined to the region of the appendix and accompanied by constipation. He had had fairly good health until 1896 when he suffered from typhoid fever, and about eight weeks after convalescence from this his troubles began with pain in the right lumbar region and "jumping pains" which worked over the hip bone into the groin of the same side. The pain was accompanied by swelling in the right iliac region, tenderness on pressure, and constipation, the symptoms being relieved by enemata, rest in bed, and careful diet. Attacks of this kind occurred about every three months until Christmas, 1899, when the intervals became shorter and the condition was more persistent. During a particularly severe attack there had been vomiting, but never any trouble with the bladder; neither had there been any great reduction in the quantity of urine passed nor other symptom pointing to the attempts of a renal calculus to travel down the ureter. The patient was treated at home by two practitioners for appendicitis, but the medical man who advised hospital treatment considered that appendicitis would not account for all the symptoms, and in this opinion, as subsequent events showed, he was correct. After a week's rest in bed without any marked symptom the patient was seen by Dr. A. M. Edge, who suggested that the mischief was renal, the urine then containing much uric acid but no blood. A few days after this there was a fresh attack of pain with marked swelling and tenderness in the right iliac fossa, and the patient suffered from sickness and constipation; the temperature was 100·8° F. and the pulse ranged from 90 to 100. Opium was given, and the bowel being washed out with a simple enema the attack subsided. An operation was then undertaken for removal of the appendix, the difficulties of the case having been carefully explained to the patient.

On opening the abdomen no adhesions and no evidence of any attack of previous appendicitis were apparent, but the appendix was unusually long and quite free and distended. It was removed and found to contain fæcal matter which was easily squeezed out of the cut end by pressure upon the distal extremity. Believing that the source of all the mischief lay in the distended appendix the abdominal wound was closed with silkworm sutures (not in layers). The patient made a good recovery, but suffered greatly from constipation. At the end of five weeks after three days' inaction of the bowels vomiting occurred and suddenly became stercoraceous. The abdomen was opened in the middle line, and although the stump of the vermiform appendix was free, the cæcum was so closely adherent to the inner surface of the first operation wound that the adhesions required cutting with scissors before the bowel could be released When this was accomplished the ascending colon was gently dragged into view and then the symptoms originally complained of were explained The colon was contracted to a size less than the calibre of the small intestine and felt thick and leathery The cæcum was distended and the contraction of the ascending colon commenced abruptly The transverse colon appeared to be normal For days the condition was most serious but eventually the patient returned home and although not fit to resume work he has kept fairly well On May 20th of this year he called to report himself He looked well and had had no recurrence of the old trouble, but he suffered greatly from sudden attacks of diarrhœa which occurred most often when solid food was taken, with soup &c, however he managed well Examination of the abdomen revealed a tendency to ventral hernia at the site of the first operation and through the thinned cicatrix active peristaltic action of the bowel could be excited by pressure of the hand and when this was done fluid could be distinctly felt passing along

CASE 2. *Hæmorrhage from the ear due to ulceration of the internal carotid, ligature of the common carotid, recurrent hæmorrhage, death* —A girl aged two and a half years was admitted into the Salford Royal Hospital on April 13th 1900, at the suggestion of the medical attendant, Dr W A. Ferguson of Pendleton and with the exception that from the right ear there was evidence of recent hæmorrhage she appeared to be well and bright and did not show any signs of pain There was no redness tenderness or swelling over the mastoid, the temperature was 101 2° F, the pulse was 96, and the respirations were 44 Immediately before admission there had been a profuse hæmorrhage which "soaked through the pillow" and was "bright red in colour" At the angle of the jaw there were enlarged glands and the tonsil of the corresponding side was enlarged The child was well nourished and did not look ill There was a large perforation in the right membrana tympani The previous history was not very clear, but according to the mother the child received an injury to the head through a fall when 12 months old and this was followed in a few weeks by a purulent discharge from the ear which soon stopped with local treatment T[illegible] on April 11th the second on [illegible] from the 13th to the 22nd th[illegible] 22nd there was a severe attack which was undoubtedly arterial in character Plugging the auditory meatus with iodoform gauze controlled the flow which came entirely from the ear and was arterial The temperature from the 14th to the 22nd had never been above 99°, but generally subnormal the pulse averaged about 74 On the 23rd a severe attack completely blanched the patient and the following day Mr Lund ligatured the common carotid. On the 25th there was hæmorrhage again from the ear at 9 50 A M, and at 1 P M there was profuse hæmorrhage from the ear, nose and mouth and death followed at 2 P M

Necropsy —At the post mortem examination which was made 24 hours afterwards, the brain and membranes were found to be perfectly healthy, there was no evidence of necrosis in the roof of the tympanum or the petrous portion of the temporal bone. The auricle being reflected forwards the floor of the bony meatus was found to be carious and perforated, and adjacent to it was a sloughing cavity of about the size of a small walnut containing recent blood clot The ligature on the common carotid was perfectly satisfactory The internal carotid communicated with the abscess cavity and had evidently given way just before its point of entrance into the bony canal, the portion of the vessel in the canal being perfectly healthy

Remarks by Mr LUND —The symptoms which simulated appendicitis in Case 1 evidently depended upon an overdistended cæcum endeavouring to unload itself into a contracted ascending colon and these symptoms originated a few weeks after convalescence from typhoid fever The distended condition of the appendix with fæcal matter and the ease with which the contents could be squeezed out convinced me for the time that its removal was called for but in this I was wrong In former cases, 33 in number, I had always found evidence of previous attacks of inflammation and in this case the appendix was quite free only distended The strong fibrous union between the cæcum and the peritoneal surface of my incision has warned me to pay more attention to careful suturing I now place my silkworm sutures at shorter intervals The prognosis is not hopeful, the contraction of the ascending colon was extreme and not confined to one spot.

In Case 2 the mischief evidently originated in the floor of the bony meatus and spreading caused ulceration of the internal carotid The perforations in the bone were not extensive enough to permit the passage of a large flow of blood but probably the cartilaginous portion of the meatus had been stripped off the bony portion allowing a free exit. The free anastomosis existing through the circle of Willis accounted for the rapid recurrence of the hæmorrhage which led to a fatal termination

Reviews and Notices of Books.

Diseases of the Upper Respiratory Tract the Nose Pharynx, and Larynx By P WATSON WILLIAMS, M D Lond, Physician in charge of the Throat Department at the Bristol Royal Infirmary, Physician to the Bristol Institute for the Deaf and Dumb Fourth edition Illustrated Bristol J Wright and Co London Simpkin, Marshall, Hamilton Kent, and Co, Limited 1901 Pp 450 Price 17*s* 6*d*

DR. WATSON WILLIAMS'S manual has so grown that it will at first glance appear to be an entirely new work, it is, however, the original work enlarged expanded, and brought up to date The present or fourth, edition contains a novel and very practical addition for at the end of the volume are no less than 12 stereoscopic photographs of anatomical preparations with explanatory text, whilst a pouch in the cover holds a handy stereoscope which if the directions given for its use are followed, will enable the reader to refresh his memory almost as well as if he had access to the specimens from which the photographs were taken

The first chapter deals with the Anatomy and Physiology of the Nose and Larynx including a short account of their development The second chapter on Examination of the Pharynx Larynx Nose and Ear with General Semeiology, contains some additions, the short description of the examination of the ear being new and not out of place The directions for investigating the various parts and for the manipulation of instruments are clear and practical and we quite agree with Dr Williams in his qualified approval of Kirstein's autoscopy The remainder of the work, which is devoted to morbid conditions, is written, generally speaking in a very able way and shows that Dr Williams is fully determined and able to keep abreast with the times and that when he shows a predilection for one side of a disputed point it is because he considers that the arguments for that view are fairly conclusive He also brings into bearing his knowledge as a physician as is especially noticeable in the short account of spurious hæmoptysis and we cannot but think that its inclusion in a work such as this one especially meant for the student, must be productive of good in directing attention to so important a point the eight lines allotted to the treatment of hæmorrhage are however inadequate

The chapter on Diphtheria is considerably lengthened and is further enriched by a very useful plate showing the various saprogenic cocci and forms of Loffler's bacillus which are depicted under various conditions and which will be valuable for reference in a doubtful case of membranous angina, the description of the clinical aspect is very good We again quite agree with Dr Williams when in discussing the relationship between tuberculosis and lupus he favours the view that the two are distinct although he does not enter at all into the reasons on which his opinion rests The tables and text dealing with the differential diagnosis of the more serious conditions of the pharynx and nose are excellent and might have been extended to diseases of the larynx

The chapter on Diseases of the Larynx leaves nothing to be desired with the exception of the point mentioned in the preceding paragraph, and it forms quite the best part of the book. Dr. Williams, after quoting the various theories as to the etiology of atrophic rhinitis, states his belief that it is of the nature of a tropho-neurosis—a view which, we believe, will be gradually accepted as the correct one, and on the question of treatment he speaks very highly of the value of cupric electrolysis. On the vexed question of the choice of an anæsthetic in the removal of adenoids in children Dr. Williams says that he prefers nitrous oxide for short operations and not too deep chloroform anæsthesia for long ones. Not too deep anæsthesia is no doubt a great point for all but slow operators, as it must diminish the risk not to push the anæsthesia too far. The space given to sarcomata of the nose occupies barely one page and we have been unable to find any mention of bleeding polypus of the septum. We are pleased to note that Dr. Williams lends the weight of his authority against the practice of applying cocaine for the relief of hay fever.

The chapter on Accessory Sinus Disease is as complete as possible, and no better description of the modes of treatment of disease of the sphenoidal sinus can be desired. Dr. Williams here gives woodcuts of his special forceps for operations on the wall of the sinus, and which give the impression of being most valuable. A useful series of formulæ is to be found in the appendix. The illustrations, both coloured and otherwise, are of the highest order and do great credit to Dr. Williams's skill as an artist. The book itself is well and clearly written and more than maintains the high standard attained by the former editions.

A Manual of School Hygiene. By Edward W. Hope, M.D. Edin., and Edgar A. Browne, F.R.C.S. Edin. The Cambridge Series for Schools and Training Colleges. Cambridge: University Press. 1901. 200 pages. Illustrated. Price 3*s.* 6*d.*

This little manual on school hygiene is in striking contrast to a work on the same subject which has recently been written by Professor Shaw of New York. Although as regards size it is less ambitious it covers far more ground and includes certain details of minor surgery and medicine which belong more fittingly to the province of the ambulance lecturer; and further, although it cannot be denied that the care of the eye is a matter of vast importance in the education of children, in a work of such limited dimensions the space which has been devoted to the optical mechanism of eyesight and its pathological disturbances is altogether out of proportion and quite possibly above the level of understanding of those for whom it is intended. Apart from these reservations little fault can be found with Part I., which comprises chapters on School Buildings, Ventilation, Warming, Feeding, &c., or with Part II., which is concerned with the Personal Hygiene of the Child. With the Appendices 1 and 2 we are entirely out of sympathy: they contain respectively the building rules as enforced by the Board of Education and the regulations and instructions by the London School Board in relation to infectious diseases in schools. These regulations are not obligatory upon, nor even always applicable to, secondary schools, and Government teachers are either provided officially with them or can have easy access to them. The chapter on School Furniture and Writing enjoins an observance of very much the same principles as are recommended by Professor Shaw, although certain sentences are curiously expressed and often difficult to understand. For instance, in writing of the influence of an ill-adjusted desk and seat on the determination of short sight and distortion of the spine it is stated that "desks should be made to fit the children and not the children the desks." As long as they "fit" either alternative seems equally satisfactory, but in any case, "even under the most favourable circumstances, sitting at a desk means a strain upon the eyes and bones of the trunk." Surely, any detriment to the child from this proceeding affects the muscles and ligaments rather than the bones. In contradistinction to Professor Shaw, who insists on a central position, the authors recommend that in writing the copybook should be in a position to the right of the middle line and "sloped upwards about 20 degrees," whatever that may mean. But if this suggestion is carried out, we gather, "the writing slopes to the right," in fact, approximates to the Spencerian script which Professor Shaw gives good reason for condemning. The concluding chapter, which deals with "Over-pressure," contains much practical advice, both as regards its recognition and as regards its treatment. Taken as a whole this manual must be regarded as very complete and up-to-date, but there is a noticeable want of proportion in the general arrangement and the literary style is neither literary nor stylish.

LIBRARY TABLE.

Clinical Lectures on Stricture of the Urethra and Enlargement of the Prostate. By P. J. Freyer, M.A., M.D., M.Ch. R.U.I., Surgeon to St. Peter's Hospital, Lieutenant-Colonel I.M.S. (retired). London: Baillière, Tindall, and Cox. 1901. Pp. 115. Price 5*s.*—This little book is composed of six lectures which were delivered at the Medical Graduates' College and Polyclinic in November last; they have appeared in The Lancet and the *Clinical Journal.* The first three deal with urethral stricture and its treatment, and that on the operative treatment of this condition is especially good. The author prefers in Wheelhouse's operation to discard the hooked staff for holding open the wound; he employs instead a flexible bougie which is passed by the meatus and projects through the wound; it is then bent upwards and both ends are held by an assistant; a loop is thus formed which holds steady the upper end of the wound. The three lectures on Enlarged Prostate are good, but the space at Mr. Freyer's disposal was hardly sufficient for a complete discussion and description of the several operative procedures which have been recommended for the radical cure or relief of this condition; and it may truly be said that this would not have been suited to the occasion when the lecture was delivered. The book is very readable.

Transactions of the American Dermatological Association at its Twenty-fourth Annual Meeting. Chicago: Pettibone and Co. 1901. Pp. 235.—Among many subjects of interest discussed at the last annual meeting of the American Dermatological Association probably the most important was blastomycetic dermatitis. Of this disease, only recognised within the last few years, already more than a dozen cases have been described and this volume contains an exhaustive pathological examination of some recent cases. Though no definite case has yet been recorded in this country there can be little doubt that the disease occurs here but has not yet been recognised. The volume contains a useful appendix of papers written during the past year by members of the association.

Functionelle Nierendiagnostik mit besonderer Berücksichtigung der Nierenchirurgie. Klinisch-Experimentelle Untersuchungen von Dr. Leopold Casper und Dr. Paul Friedrich Richter. Mit 2 Holzschnitten. *(Functional Diagnosis of the Kidneys with special reference to Renal Surgery.)* Berlin and Vienna: Urban and Schwarzenberg. 1901. Pp. 156. Price 4 marks.—It is difficult to overestimate the importance in the surgery of the kidneys of a correct diagnosis of the renal condition, and especially of an exact knowledge of the relative efficiency of the two kidneys, for it may well be that the kidney which appears to be the more severely affected may yet be the one which is chiefly carrying on the work of excretion and removal of this kidney would be followed inevitably by a fatal result. Such an occurrence has doubtlessly many times followed a nephrectomy performed with an insufficient knowledge of the relative capabilities of the two kidneys. Ureteral catherisation has been of the greatest service in this connexion. The possibility also of the absence of one kidney must be carefully considered before a nephrectomy is undertaken. This work contains a clear account of the methods by which the functional efficiency of the kidneys can be investigated and is well worthy of study by those who are specially interested in this branch of surgery, but its subject should be well considered by all who have to operate at any time on the kidney or ureter The authors give notes of 90 cases in which they have investigated the condition of the kidneys and of the urine

A Manual of Hygiene and Sanitation By SENECA EGBERT, A.M., M.D. Second edition, enlarged, and thoroughly revised London Henry Kimpton. 1901 Pp 436 Price 10*s* 6*d*—This book deals with both practical and general considerations It contains chapters on Bacteriology and Chemistry as applied to the examination and analysis of food and water It also deals with personal as well as public health and one interesting feature is a chapter on School Hygiene There is also a good chapter on Disinfection and Quarantine in which the efficient disinfectants are described The chapter on Stimulants and Beverages is written in a very sensible strain and especially the section on Alcohol In dealing with the Impurities of the Air the author makes no reference to the excellent work of Dr J S Haldane on carbonic oxide poisoning He merely states that cases of poisoning by carbon monoxide are much more serious than by carbon dioxide and then adds that recovery from the effects of the former is slow and uncertain because this gas unites with the hæmoglobin of the red blood corpuscles, paralysing them as it were, and rendering them unable longer to act as oxygen carriers to the tissues Now it is well known that sometimes extraordinarily rapid recoveries occur in cases of acute poisoning by coal gas, owing to the fact that the blood in the veins and most of the organs becomes only very partially saturated in cases of suffocation by gas containing carbon monoxide but no oxygen As soon as the coal gas is removed from the lungs and a plentiful supply of oxygen or air is substituted for it the unsaturated venous blood still slowly entering the lungs takes up oxygen abundantly and so causes rapid recovery as soon as it reaches the tissues Dr Haldane found that from experiments on himself about six hours are required for the carbon monoxide to disappear entirely from the blood in severe cases of poisoning The work is based on American practice, but its pages may be read with distinct advantage by students of hygiene in this country It is well written clear, and covers a somewhat surprising expanse of subject considering the size of the volume

New Inventions.

THE KANNENBEER PROCESS OF PRESERVING BEER.

BEER is only a wholesome beverage when it is in good condition, assuming of course that it is made from irreproachable materials It must be admitted that our present methods of storing and preserving beer are open to considerable criticism not only from the point of view of health but from the economic point of view also. Beer in cask, for example is seldom sound to the last few pints owing to the access of air through the vent-peg orifice and to the accumulation of a sediment which is very prone to decompose. Bottled beer, again, is exposed to the disturbing influences of light, while it is not easy to detect or to remove any uncleanliness that may exist. There is, therefore, much to be said in favour of the system of keeping beer in air tight and light tight jugs as in the Kannenbeer process. Before, however, the beer can be "bottled" by this process it is necessary to devote some attention to its condition In fact it is found that to secure good results the best beer must be used and that special care must be taken to bring it to a desirable point of maturity Otherwise the beer would not keep in sound condition and would probably throw a sediment, both of which disadvantages the Kannenbeer process is expressly designed to obviate and, as a matter of fact, does obviate according to our experience We have recently witnessed the process and it is well worth describing, as being a very praiseworthy endeavour to produce a beverage that will satisfy sanitary requirements. The beer is matured at the same stores as those where the "bottling is done The maturing process is slow, [illegible] three months During this time [illegible] a fine brilliant appearance and [illegible] flavours of well brewed beer when in excellent condition. The beer is next carefully filtered—a very important step in the process All this time the beer is kept quite cold The beer is then run into the "*kanne*" or jug, which holds a quart, without coming into contact with air The jug is then closed by a lid pressing tightly by means of a spring upon a clean rubber cushion The beer is thus kept away from the air and from the light, both of which are important factors in destroying the sound condition of beer Each jug is then wrapped in paper to protect it from dust and dirt and so that it may look perfectly clean on the table The process is not limited to one kind of beer, ale, stout, and lager being treated in a similar way It is easy to reckon up the unquestionable advantages of this method. It seems to us not only to secure the beer against contamination and change, but to avoid certain unpleasant possibilities in the case of beer stored in other ways The consumer can easily see for himself that the jug is clean and he will not be slow to appreciate the advantage of *having beer on draught so to speak* (without any objectionable excess of carbonic acid gas) always in sound healthy condition Moreover the jug will be less likely than is a bottle to be used for the receptacle of poisonous metal polish carbolic acid, and other objectionable and dangerous contents The method has our approval, therefore on many grounds and particularly from the sanitary standpoint The agency is at 17, Philpot lane London E C

CHESTERFIELD MEDAL FOR DERMATOLOGY —The Chesterfield medal for dermatology, given under certain conditions as the result of a competitive examination at St. John's Hospital for Diseases of the Skin London has this year been awarded to Mr George Norman Meachen M B, B S Lond clinical assistant to the Hospital for Diseases of the Skin Blackfriars.

DENTAL HOSPITAL OF LONDON —On August 1st, in the new hospital Leicester square, which was opened in March last a conversazione was held and the prizes were distributed to the students of the hospital The visitors, who numbered about 400 were received by Mr T Arnold Rogers Mr J Smith Turner, Dr Walker, and members of the staff Mr Morton Smale in opening the proceedings stated that the King had acceded to the request to grant his patronage to the hospital Mr Smale referred to the great success that had attended the affiliation of the hospital with the London University as a teaching school and remarked that 53 students had entered during the year the largest number recorded in the history of the institution. It was announced that the Walker scholarship had been awarded to Mr L C Sprawson and that Mr G Sheppard had gained both the Founders scholarship and the Ash prize Mr Rogers stated that the new building owed its existence largely to the indefatigable energy of Mr Morton Smale who in company with Mr F Lloyd Williams had during the year visited the United States to study the developments in dental teaching in that country

THE LANCET.

LONDON: SATURDAY, AUGUST 10, 1901.

The Interim Report of the Royal Commission on Sewage Disposal.

Owing to the very great pressure upon our columns last week and the previous week we have been able to allude in only brief terms to the interim report of the Commissioners appointed in 1898 "to inquire and to report what methods of treating and disposing of sewage may properly be adopted." In our issue of July 27th we noted without comment the more important conclusions to which the Commissioners at this stage of the inquiry have come and which they have thought it desirable to make known. The difficulties of the inquiry may be judged from the fact that this interim report, which refers to three questions which appear to be of urgent importance, is the first pronouncement that has been made since the appointment of the Royal Commission three years ago. The consideration of the second item of the terms of reference has so far made it impossible for the Commission to arrive at any riper result than that which the interim report shows. This particular form of reference requires the Commissioners to inquire and to report "if more than one method may be so adopted, by what rules, in relation to the nature or volume of sewage, or the population to be served, or other varying circumstances or requirements, should the particular method of treatment and disposal to be adopted be determined." In order to supply a complete and definite answer to this somewhat comprehensive request nothing short of a technical research was involved. The Commissioners admit as much, and no one knowing anything at all of the intricacy of the problem could expect them at this stage to pretend that in the time so far allotted to them they had the smallest chance of coming to a satisfactory conclusion. They have found it necessary to institute a number of scientific investigations which have been entrusted to Professor Boyce and Dr. A. C. Houston, representing the bacteriological side, Dr. McGowan and Mr. Colin Frye, representing the chemical side, and Mr. G. B. Kershaw, representing the not least important aspect of the question, the engineering side. We think that already a distinct impression has been made upon the Commissioners in favour of the treatment of sewage by bacteriological methods. Indeed, if we are not mistaken, we read a conviction in their minds that the bacteriological method at any rate is effectual in breaking down offensive matters into innocuous products when attention is paid to the requirements of the specific micro-scavenger concerned, but that at present they have no sure and certain evidence that pathogenic bacteria do not survive the process. This is very much in a line with the valuable observations of Dr. Houston in connexion with the London County Council experiments at Barking and Crossness on coke-bed filtration. The subject requires careful extended investigation.

But this interim report is not a series of negatives by any means; it contains valuable conclusions. Thus the Commissioners doubt whether any land is useless for the purification of sewage, though in the case of stiff clay and peat lands the power to purify sewage seems to depend on the depth of the top soil. This description of land, however, is pretty certain to offer difficulties if not to render land treatment impracticable. Next the Commissioners are satisfied that it is practicable to produce by artificial processes alone, either from sewage or from certain mixtures of sewage and trade refuse (not even omitting the cases of Leeds and Manchester) effluents which will not putrefy, which would be classed as good according to ordinary chemical standards, and which might be discharged into a stream without fear of creating a nuisance. In view of this conclusion the Commissioners are led to recommend that the present rule of the Local Government Board should be relaxed under proper safeguards and that in some cases the application of treated sewage to lands might be omitted. We have expressed the opinion that such treatment is often not only superfluous but prejudicial. The Local Government Board rule was promulgated at a time when the efficiency of bacteriological treatment was not realised. The adoption of the new recommendation of the Commissioners will remove what has proved to be a source of embarrassment to processes of treating sewage by bacterial agencies which are known to be of certain efficiency. It will further augment the economy of all such processes. It may be noticed that the Commissioners employ the term "artificial processes" as applied to the purification of sewage by bacteria. We confess to being nonplussed by the employment of the word "artificial" in this connexion. Surely, nothing is more natural than that the functions of bacteria should be induced to begin, to continue, and to end the work of purification of human excreta. Is not the teaching of the great natural processes convincing that to micro-organisms is relegated the work of breaking down complex offensive matters into simple and not only harmless but positively beneficial products? Why, then, is the cultivation of bacteria for this purpose regarded as an "artificial process"? We can quite understand chemical treatment, on the other hand, being regarded as such.

A most important clause occurs in the third conclusion of the report. The Commissioners express the opinion that the general protection of our rivers is a matter of such grave concern as to demand the creation of a separate commission, or a new department of the Local Government Board, which shall be a supreme "rivers authority," dealing with matters relating to rivers and their purification, and which, when appeal is made to it, shall have power to take action in cases where the local authorities have failed to do so. We cordially agree that some such authority as is here suggested should be appointed for the express control of the purification of rivers, but, assuming that we interpret the recommendation accurately, we cannot see the necessity for the creation of a separate commission to decide this matter The present Royal Commission is so well composed that the Government would be well advised, in our opinion, to add at this stage a fresh term of reference for the consideration of this Commission, to the effect that the Commissioners should be required to make, as they are highly qualified to do, a definite and practical recommendation on the question. It is, after all, but an extension or sequel of the subject with which they have been asked immediately and in the first instance to deal

Home Nursing in Chronic Cases.

IT is proposed that the women's memorial to QUEEN VICTORIA *should take the form of a national subscription* on behalf of Queen Victoria's Jubilee Institute for Nurses, founded by Her late Majesty in 1887 with the money of the women's offering of that year There is much to be said in favour of such a scheme The beds of many of our hospitals *are crowded with cases which could be treated* with equal benefit in their own homes and large numbers of patients, who would gain immensely in hospital, are kept waiting for admission for an indefinite time, perhaps until it is too late for relief Neither the public nor hospital officials seem quite to appreciate the fact that a general hospital is not a home of rest, but a place where active therapeutic measures can be taken with a chance of success

Cases of anæmia are found in hospital wards with unnecessary frequency Many sufferers from dermatitis are best treated at their own homes, particularly those who present varieties of disease where pus organisms, or some special forms of organisms, are adding to, or are entirely answerable for, their state Those forms of eczema which require rest in bed can be treated in any clean environment Given fair sanitary surroundings cases of carbuncle or boil can be well treated outside, and are certainly not wanted inside, a crowded building Ulcers of the leg need seldom be treated in a hospital, nor in these days of improved treatment should they be allowed to be neglected Firm believers in the oxygen treatment of ulcers of the leg would argue for their admission into a hospital ward, but it has still to be proved that this method of treatment has much quicker or more permanent results than have *many other less expensive methods In cases of* malignant disease of the womb or of the breast and indeed, also, of other organs unsuitable for operation, the patients are often left to die in a pitiable condition. Here the services of a nurse are invaluable at the patient's home, while hospital treatment is too often quite useless Patients suffering from pneumonia or bronchitis complicating measles cannot readily be allowed admission into a hospital on account of the general infectiousness of the zymotic complaint, but theirs are pre-eminently cases requiring such skilled nursing as they can get. Again, the sequelæ of scarlet fever, such as rheumatism, albuminuria, and otitis, lend themselves readily to assistance at the hands of a visiting nurse In such instances she is helping to dispel the prolonged after mischief which would render the sufferer a more or less useless member of society and a constant anxiety to his friends Paralytic cases of long standing and incurable cases of injury are very ready to fall into a slough of despondency· Many of these patients still cling to life Hospital finances will not stand the strain of maintaining them and it is often cruel to send them into the workhouse Some gentle encouragement and a little skill on the part of a nurse proffered at the patient's own home, will undoubtedly mitigate the severity of the symptoms and cheer up these miserable sufferers

Lastly, if a special nurse can be told off for the duty, cases of ordinary zymotic disease can be fairly well looked after in the homes of the poor, where the medical officer of health can be satisfied as to proper isolation. It is often impossible to get such cases admitted into special hospitals, but where a spread of infection can be avoided home treatment will generally suffice The good done by the Queen's nurses is of a kind apart from that done by the hospital. They assist hospital finance, they save much unnecessary hospital labour They do a special work for humanity in that the bulk of the suffering creatures whom they relieve are not suitable hospital inmates and are also unfit for, or are very undesirous of going into, the workhouse infirmaries It is to be hoped, therefore, that *the attempt to raise a national subscription* will be met by a hearty response from the women of Great Britain Certainly it would not be possible to think of any more suitable way of honouring the name and memory of our late great Queen than by assisting the funds of the Jubilee Institute for Nurses The ministrations of the Jubilee nurses make for the preservation of exactly that sanctity and privacy of family life which QUEEN VICTORIA was known to prize so highly

Indian Ophthalmic Practice.

A VERY interesting number of the *Indian Medical Gazette* has recently been published under the title of "Special Ophthalmic Number giving the experience of surgeons in various parts of India in the treatment of diseases of the eye, and particularly in regard to the operations for cataract The prevalence of this affection amongst the natives of India may be in some measure estimated from the fact that in 1896 Lieutenant-Colonel F H POPE, I M S, the superintendent of the Ophthalmic Hospital, Madras, had operated on 4000 cases and that since that date he *has operated* upon upwards of 3000 more Again, Major H HERBERT, I M S the ophthalmic surgeon in charge of the Ophthalmic Hospital, Bombay, has performed during the last five years 578 extractions, Major F P MAYNARD, I M S, civil surgeon of Patna, has done 300 extractions; at the Mayo Hospital Jaipur during the years 1891-1900, Colonel T H HENDLEY, I M S, C I E, and Lieutenant-Colonel P DURRELL PANK I M S, performed no less than 5310 extractions including 304 by Assistant Surgeon DA GANG SINGH and 93 by various other operators; Captain HENRY SMITH I M S, civil surgeon of Jullunder, Punjab records *1694* cataract operations *performed in* 10 years and in the last 11 months 1050 more, Dr ERNEST NEVE has done 936 in 20 years of which 725 were performed during the last 11 years, Major C R M. GREEN, I M S, at Mozufferpur, has had a *total* of 425 operations; Major J. MORWOOD, I.M.S., has had 1523 operations for cataract; Mr. CHARLES MACNAMARA, F.R.C.S., I.M.S., had had 350 cases of linear extraction, but this was antecedent to 1867; Brigade-Surgeon E. F. DRAKE-BROCKMAN, F.R.C.S., I.M.S., shortly after that date tabulated 3393 cases; and Dr. W. J. WANLESS, in charge of the American Presbyterian Mission Hospital, Miraj, Western India, has had 495 operations.

Thus it appears that this small number of surgeons in the course of a very few years operated upon nearly 25,000 cases of cataract. European statistics of 100 and 200 cases, which leading ophthalmic surgeons regard as a large number, pale beside these immense numbers. What is still more remarkable is that the results are excellent. Lieutenant-Colonel POPE remarks apologetically that it often happens in the Madras Hospital that a run of 300 successful cases occurs, which seems extraordinary, but that immediately following this four or five cases fail either from suppuration or severe irido-cyclitis or from some unknown cause, and so the average success at once falls. There are few European surgeons who would not be well content to point to a register of 300 consecutive successful cases. The accounts of the methods adopted given by each of the operators mentioned above are full of interest. Lieutenant-Colonel POPE uses atropine before operating to determine the relations of the iris to the underlying lens. He sterilises both the conjunctival sac and the instruments. He divides the capsule with a needle and then performs an extraction without an iridectomy, the incision being a large one, considerably exceeding the three-millimetre incision of VON GRAEFE. A conjunctival flap is always made, as a result of which he finds prolapse of the iris almost a thing of the past. A pad and bandage are kept on for a day or two. Exposure of the eye to the air he thinks a distinct advance in the hygienic treatment of the wound. If conjunctival catarrh follows the operation he cleanses the eye with saturated boric acid solution and then applies a solution of nitrate of silver of the strength of three grains to the ounce of distilled water. If suppurative keratitis supervene he employs atropine in addition to the above remedies, and if irido-cyclitis remain he recommends excision, fearing sympathetic inflammation of the opposite eye.

The practice in India seems to be to extract without iridectomy. Thus Lieutenant-Colonel J. T. LEWTAS, I.M.S., Professor of Ophthalmology, Medical College, Calcutta, states that of 147 operations iridectomy was done in 33, and then only because some object was to be fulfilled by it. Lieutenant-Colonel LEWTAS uses a moist aseptic pad for three or four days. Major HERBERT recommends the cleansing of the conjunctival sac before operating with a solution (1 in 3000) of corrosive sublimate. Both he and Major MAYNARD frequently operate without iridectomy. Captain HENRY SMITH in the immense majority of his cases operates without iridectomy but extracts the lens in the capsule, and his results in a total of 1650 cases are excellent. The same practice is pursued by Dr. WANLESS who sharpens his own knives. Lieutenant-Colonel POPE, who has given up this method after trying it for some time, thinks that there must be something different in the size, formation, and firmness of structure of the eyes of the natives of the north of India as compared with those of the south, because he finds insuperable difficulty in making the lens start from its position, whilst on firm pressure being applied the vitreous humour escapes. Captain HENRY SMITH's paper deserves careful perusal.

We congratulate our contemporary upon having collected such an extremely interesting and valuable series of articles from leading Indian surgeons. They will be read with the greatest interest in this country, and although some differences probably exist between the eyes of the native of India and those of the European, yet there are many lessons to be learnt from these very able and personal memoirs in regard to the particular methods of operating that have been found most successful, as well as the preliminary and after-treatment that should be adopted. The medical profession at home is always gratified to read of, and to learn from, the experiences of colleagues abroad; and we make no doubt that as Greater Britain, under a more enlightened comprehension of the real significance of a civilised empire, becomes more closely knit together into an entity, these interchanges of scientific information will become more frequent.

Annotations.

"Ne quid nimis."

THE DEATH OF THE EMPRESS FREDERICK.

THE struggle against the inevitable so long and so bravely carried on by the eldest daughter of Queen Victoria is over and the Empress Frederick is dead. It has been an open secret for at least a twelvemonth that the Imperial patient was suffering from malignant disease, but it had always been her desire that her condition should not be discussed. She shrank from sympathy and faced her position in courageous silence. When it was seen that she was too ill at the beginning of the year to take her place with her brothers and sisters at the bedside of her dying mother it was felt by everyone that the end could not be far distant, and now it has come. By the mercy of Providence the closing scene was peaceful and the death-bed painless.

THE FEES OF MEDICAL WITNESSES.

ON Monday last, Mr. W. F. Lawrence, one of the Members for Liverpool, raised in the House of Commons, on the Home Office vote, the question of the fees paid to medical witnesses. In a well-informed and temperate speech he pointed out that the scale of fees at present received by the medical profession, as laid down by an old Act of Parliament, was in these days completely inadequate. Mr. Ritchie, following the suit of a late distinguished Home Secretary, Mr. Asquith, allowed that the fees granted to medical witnesses in England were not generous and compared unfavourably with those granted in Scotland, but, like Mr. Asquith, he could not entertain the question of revision because to do so would lead to the consideration of the whole scale of fees paid to all classes of professional witnesses. There was once a young nobleman in a popular farce who used to say on all occasions to everyone who addressed him, "What rot," and we feel strongly tempted to say so to Mr. Ritchie. Medical witnesses are much more required in courts of justice than any other professional witnesses and their duties are not similar. There need be no delay in considering their case apart if the Home Office would make up its mind to take the trouble. Of course, someone would have to do a little work and this, no doubt, is a formidable thing for a Minister to contemplate, but our point is that the work need not be magnified into an impossibility and then neglected. The fees of medical witnesses should be revised.

THE FILTERS SUPPLIED TO THE TROOPS IN SOUTH AFRICA.

CONSIDERABLE discussion is taking place in public health circles as to the merits of the filters supplied to the troops in the South African campaign. It is stated that the filters decided upon by the War Office showed a lower efficiency than the existing standard and that they were permeable to the typhoid bacillus. If this be so it is evident, considering the enteric fever from which many of our soldiers suffered, that they were given a false sense of security in regard to this matter. These allegations, it seems to us, should be thoroughly sifted, and yet another explanation of the action of the War Office is called for. The probability is that no portable filter can be regarded as secure in the excessively trying conditions under which our troops conducted the campaign. It was difficult enough to find water to drink, and how under such circumstances could the filters be periodically cleansed and sterilised? The evidence of laboratory experiments is worth very little in such a case and some method of purification of water other than filtration, such as sterilisation by the addition of sodium bisulphate, seems indicated. We trust, however, that the matter will be duly investigated.

FATAL INTESTINAL HÆMORRHAGE IN BRIGHT'S DISEASE.

AT the meeting of the Société Médicale des Hôpitaux of Paris on June 28th Dr. M. A. Souques related the following case. A man, aged 58 years, was admitted to hospital with albuminuria which he appeared to have had for five years. Some months previously his urine was examined and contained 0·3 centigramme of albumin to the litre. He looked strong, but his legs were œdematous and his abdomen was swollen and a little painful and tender. The heart was hypertrophied, the pulse was 120 and small, and the temperature was 101° F. In the chest there were sonorous and sibilant râles. There were diarrhœa and albuminuria. Bright's disease with slight uræmia was diagnosed and milk and dry cupping were prescribed. Though the patient was apparently in a good condition he died on the following morning. There had been vomiting during the night and some diarrhœa and slight delirium. The necropsy showed that death was due to intestinal hæmorrhage. The ileum was uniformly blackish for an extent of one and a half metres. In this part it was filled with black fluid and the mucous membrane was hæmorrhagic and livid. All the intestinal coats were tinged with blood, and even a small quantity of ascitic fluid which was present was reddened. The most careful examination of the mucous membrane *of the affected part* did not reveal any ulceration. The stomach and the rest of the intestines were normal. There was no venous thrombosis. The kidneys were large and each weighed 250 grammes. The section had the appearance of large white kidney. The capsules were adherent in places. The lungs were œdematous and congested. The heart had the typical aspect of *cor bovinum*; the left ventricle was greatly hypertrophied. In this case death resulted from an intestinal hæmorrhage which had not had time to show itself externally. Intestinal *hæmorrhage in Bright's disease is now well recognised*, but writers simply mention it without entering into details. Cases such as the present have been rarely recorded. Rayer[1] has described the following one. A man aged 48 years succumbed to a second attack of nephritis with melæna. The necropsy showed signs of pleurisy and hæmorrhagic peritonitis. In the peritoneum were several litres of red serous fluid. The ileum and large intestine were black; on the mucous membrane were fibrinous clots. The intestinal contents *were blackish and liquid*. Freitz, who has specially studied the gastro-intestinal troubles of nephritis, has found intestinal lesions in 209 out of 220 cases of uræmia. In 27 cases there was "dysentery," croupous or ulcerative; in four there were effusions of blood into the intestine. Aufrecht has described a case of Bright's disease with Cheyne-Stokes respiration in which repeated and abundant intestinal hæmorrhages took place for a week.[2] Intestinal hæmorrhage in Bright's disease is of two clinical types. In one, the most *frequent, there is intestinal ulceration*; in the other there is simply hæmorrhage, more or less abundant, which may show itself externally or not. Hæmorrhage without ulceration can be explained by intestinal congestion and rupture of capillaries. As to the mechanism, it has been shown that toxins, for example the diphtheritic, will cause intestinal hæmorrhage in animals. No doubt during their elimination by the intestine they produce congestion. In uræmia toxic substances are eliminated by the intestine, possibly with the same result.

THE CRIPPLES' MISSION.

THERE are several societies the objects of which are to provide the children who live in the slums and poorer neighbourhoods of London with an annual holiday, but poor crippled children of whom we believe there are about *6300* in our vast metropolis, are unable by reason of their deformities to join in the holidays and treats which are provided for them by people who possess both money and kind hearts. The Cripples' Mission, which is a development of the Ragged School Union and Shaftesbury Society, sends every week from 50 to 100 helpless boys and girls to the seaside for a stay of two or more weeks. Other parties of equal number are conveyed for the day to Epping Forest or to one of the parks. In connexion with this mission we are glad to see that a new holiday home for cripples was recently opened at Margate, Gordon House, the old home of the Young Men's Christian Association having been renovated at a cost of £400. It possesses accommodation for 30 beds. The offices of the Cripples' Mission are at 32, John street, London, W.C. The society looks after the children until they are of the age of 16 years.

THE RAPID DETECTION OF BORIC ACID IN MILK.

THE *usual methods employed for the detection of boric* acid in milk (the turmeric test and the alcohol and glycerol flame tests) in order to be delicate require a preliminary evaporation and incineration. Though this presents no difficulty in the laboratory, it renders the tests somewhat impracticable in the many cases where it may be desirable to make a test on the spot. Mr. Droop Richmond, F.I.C., points out that there is a reaction peculiar to boric acid which may be employed as a test; in aqueous solution boric acid hydrolyses almost completely into B_2O_3 and H_2O, and is therefore hardly acid to phenolphthalein, which he has proved by cryoscopic determinations of the molecular weight in aqueous solution. Re-combination is effected by the addition to the solution of polyhydric alcohols. Thus as R. T. Thompson was the first to point out, boric acid could be titrated with phenolphthalein in a 30 per cent. glycerol solution, showing that it is completely re-combined. No other acid possesses this property. Milk sugar behaves as a polyhydric alcohol and in 4 to 5 per cent. solution causes re-combination to the extent of about two-thirds. This peculiar behaviour of boric acid may be taken advantage of to test for its presence in milk. A portion of milk, say from 10 to 20 cubic centimetres, is placed in a beaker or other vessel, a drop or two of phenolphthalein solution added, and caustic soda solution (about normal strength) dropped in cautiously till a faint pink colour appears; a little of the milk is poured into two test-tubes, to one an equal bulk of a neutral 50 per cent. glycerol solution is added, and to the other an equal bulk of distilled water. If the milk be free from boric acid no difference of colour between the two tubes is noticed; in the presence of boric acid the glycerol tube will become paler, or usually white, while the water tube will become distinctly pinker. Any difference in colour between the two tubes (except the faint difference due to the greater transparency of the mixture of milk and glycerol) indicates the presence of boric acid. The neutral glycerol solution is prepared by mixing equal volumes of glycerol and water, adding a few drops of phenolphthalein and dropping in caustic soda solution till a very faint pink colour appears.

THE PROPER HOLIDAY.

At a time when the subject uppermost in the minds of men who work is their holiday we naturally pause to reflect how that interval of freedom is generally spent, and whether it is always of as great benefit as it should be. It is a very common thing for people to return from their holiday in worse health than when they left. This is deplorable and should seldom occur. The reason for such an unfortunate and entirely unintended sequel to a period of recreation is sometimes easy to find. Enchanted and blinded, perhaps, by the delights of some sequestered house, long solitary and little used, in the heart of a rural district, the weary holiday-maker from town ignores the evils of an antiquated sanitary arrangement, and while feasting his eyes on the charms of fruit trees and ivy-covered walls inhales the poison of a septic throat, or returns home to find his children fall ill with diphtheria reaped at that charming country resort. Let the man, then, who seeks the quiet of unfrequented country places as a main feature of his holiday at any rate take care that hygiene has not been sacrificed to antiquity. It is possible to find houses that are both interesting and old although the drainage is new and effective. In the matter of drainage we may well prefer a modernity which we avoid in the other features of our holiday house. It is a wise step for those who work in the bustle and clatter of a large town thus to rusticate themselves in their time of recreation One of the most essential features, in fact, of a holiday is that it should be a change. A recognition of this fact leads the medical practitioner of the country to take his holiday in a manner very different from that which appeals to his city brother. We know such a gentleman, busy day after day in his trap, his motor-car, or on his bicycle over a wide agricultural district, who finds one of the charms of his holiday in travelling about London on the underground railway. It is a form of entertainment rarely sought after from motives of pure enjoyment. Yet we are sure our country friend is quite right in his argument and the success of his method is proved by the renewed vigour and interest with which he returns home. He has had a change. Those whose lives are sedentary should exercise themselves when on their holiday, while he who is always running about when at work will do well to lie on his back on the soft meadow or, pillowed by the shelving beach, listen to the lazy lapping of the waves. We have no approval for the historic omnibus driver who when he had a "day off" spent it beside the comrade driving another 'bus. It is a trite enough observation that a holiday should be a change, yet it is one very often disregarded. Men become so moulded into the habits which they form that, though conscious of the advantage of a temporary cessation of their usual activities, they do not make the effort to secure it. The hard reader takes his books with him, the man who is always on his legs goes away and climbs, few seek as recreation the opposite of their usual occupation, and many a holiday longed for as the opportunity for renewing health and vigour turns out a disappointment because the time was not spent with that alteration of interest that should be the feature of all real leisure

UNIFORM MEDICAL LEGISLATION IN AMERICA.

Dr. Emil Amberg, of Detroit, Michigan, has sent us an article condemnatory of the system, according to which, in America, "many States absolutely refuse, within their jurisdiction, the license to practise to the same physicians whom citizens of other States legally authorise to exercise their professional duties, and to whom they intrust their own lives and those of their families." This fact, he says, can be explained in only two ways. Either the standing of those physicians is not sufficiently high for the former States, or the former States intend to protect their "home industry." He also considers that it would be a wise step to close about three-fourths of the medical schools now existing and either to place the rest under rigid State control or to make them State institutions.

THE ARMY MEDICAL SERVICE.

In April of this year a sub-committee of the Parliamentary Bills Committee of the British Medical Association issued a report on, and recommendations for, the reorganisation of the Army Medical Service. This report was adopted by the Council of the Association and a copy was forwarded to the War Office. Some addenda were appended to the report concerning the proposed amalgamation of the British with the Indian Medical Service, and in the last paragraph of these addenda it was stated that the sub-committee were "of opinion, in order that our British and Indian soldiers may in time of peace and of war be kept in the best possible physical condition—that is, in health and fitness to perform their duty—it is necessary that they should be under the care of a single medical service, with one portal of admission." Without at present entering upon the debateable question as to whether or not it is desirable that the two services should be amalgamated, we understand that, so far as is known, there is no intention on the part of either the home Government or the Government of India to amalgamate the two services; nor would any such scheme be considered.

THE ANNUAL REPORT OF THE COMMISSIONERS IN LUNACY.

The report of the Commissioners in Lunacy for the year 1900 has been issued in the form of a Blue-book. The total number of lunatics under the notice of the Commissioners on Jan. 1st, 1901, was 107,944. This was an increase of 1333 for the year 1900, as against an increase of 1525 in 1899 and of 3114 in 1898. The average annual increase for the last five years has been 2300, so the increase for 1900 is by no means large. The numbers of patients in county and borough asylums, registered hospitals, Broadmoor Criminal Lunatic Asylum, and of single patients have increased, while those in licensed houses, naval and military hospitals, metropolitan district asylums, and workhouses have decreased. The Commissioners point out that as regards asylums they have noticed extravagance in sundry details, and they further say that when plans are submitted to them in which any departure appears from the principles of due economy, proper regard being had to adequacy of buildings and a sufficiency of decoration they shall regard it as their duty to advise the Secretary of State to refuse his approval of the plans. We are glad to see that there is a decrease in the number of lunatics in workhouses. The workhouse as at present constituted is quite unfit for the reception of lunatics. The Commissioners, we are glad to see, suggest a differentiation of asylums. The inexpensive and more simply fitted are to be used only for the infirm, while the more adequately equipped hospitals are to be used for the more acute cases.

THE USE OF CATS' AND DOGS' MEAT FOR SAUSAGES.

RAILWAY arches have doubtless been put to multitudinous uses from time to time and more particularly in the neighbourhood of London where they may be seen serving the purpose of a stable or a church. The sanitary inspector of Bethnal Green has, however, been devoting his attention to the operations beneath an archway in that part of London. About a year ago certain persons were prosecuted and heavily fined for selling and using for human food material purchased from a cats' and dogs' meat dealer, the lessee of a railway arch, and somewhat similar mysteries have again been enacted in the same neighbourhood, but outside the district of Bethnal Green. It appeared for a long time that the cats' meat trade had ceased but by means of a midnight vigil the sanitary inspector ascertained that the cats' meat was removed surreptitiously to a small private house from which it was fetched by makers of sausages. After considerable trouble a butcher in Hackney was followed home with a consignment of this material which on arrival at the butcher's premises was seized and condemned. We are glad to hear that further legal proceedings are impending. *The inspector is of opinion that an enormous* amount of this objectionable substance, highly seasoned with condiments, and perhaps we would add, temptingly coloured, is dealt with and that regular markets exist for the trade. Unfortunately the trade is carried on in several districts, and hence there is need for the officers of some central authority such as the London County Council, to take the matter up. Sausage factories need much watching in this country, and sausages introduced from abroad need more analysis than, we fear, they get at present. What is required is the right of entry into all places in which food or substances used for the preparation of food are made ready for the market. Such a procedure is better than much analysis.

THE SEXUAL SENSE IN GENERAL PARALYTICS

LITTLE has been known hitherto regarding the variations of the sexual feeling in general paralysis of the insane. In the *Archives de Neurologie* for July Dr. Marandon de Montyel describes the exact clinical conditions in the three stages of general paralysis and draws certain new and interesting conclusions. The total number of patients whose cases were investigated was 1037 of whom 727 were of the "expansive" type, 162 of the "depressed" type, and 148 of the mixed type, as regards psychical symptoms. The following table *gives the conditions of the sexual sense whether normal* heightened or lowered in the three types of cases:—

Clinical type	Normal sexual sense Per cent	Heightened sexual sense Per cent	Lowered sexual sense Per cent
a Expansive	11 5	18·2	70 3
b Depressed	0 0	0 0	100 0
c Mixed	4 7	19·6	75 7

The most characteristic feature is that every one of the 162 patients of the depressed clinical type showed a lowered activity of the sexual instinct while even in the expansive type of patients 70 per cent showed the same. "It is not then true to pretend," says Dr. Marandon de Montyel, "that the self-satisfaction of general paralytics and their delusions of physical strength are engendered by a genital superactivity." Investigation was also made as regards sensibility to pain and it was found that this sense was more often altered than the tactile sensibility of the genital organs. From a detailed examination and tabulation of cases, however, no connexion could be established between alteration *of the algesic sense (cutaneous sensibility to pain) and* impotence. The general paralytic may, and often does, brag of his virile power while impotent. It was also found that as regards etiology the operation of alcohol was that which caused most of the alterations of the genital sense. These genital alterations had no prognostic value, but if they appeared early—that is in the prodromal stages of the disease—they might have a distinct diagnostic value.

THE BRITISH DENTAL ASSOCIATION

AT the annual general meeting of the British Dental Association which was opened on August 3rd some interesting points were raised. The honorary secretary, Mr. W. B. Paterson, in his annual report mentioned that the efforts of the Association in regard to the care of the teeth of sailors and soldiers had been met by the naval authorities by the purchase of "dental outfits" for naval surgeons. No doubt, continued the report, the outfits are suitable for the purpose for which they are intended but then a box of tools does not necessarily make a workman. The army authorities, however, had recognised the necessity for dental aid for troops on active service and had applied to the Association to supply four dental surgeons to go out to South Africa for the purpose of attending on the troops. Mr. S. J. Hutchinson, the President of the Association, referred in his presidential address to the good work of the School Dentists' Society and remarked that it was greatly to be regretted that the School Board for London had not availed itself of such opportunities as it might have done for the proper supervision of the teeth of children under its care. He referred with satisfaction to the fact of there being four dental surgeons at the seat of war and expressed a hope that in future a dental department would be seen working in unison with the *Royal Army Medical Corps*. The annual dinner of the Association was held in the evening and among the guests were Mr. H. G. Howse, the President of the Royal College of Surgeons of England, Dr. C. Godon, President of the École Dentaire, Paris, and Sir James Crichton Browne.

HÆMORRHAGE IN CHRONIC JAUNDICE

IN *American Medicine* of April 27th Professor Osler calls attention to the frequency and seriousness of hæmorrhage in chronic jaundice. In the past few months he had observed five cases in the Johns Hopkins Hospital. In Case 1 a woman was admitted on Jan. 9th with jaundice of four months' duration. There were recurring attacks of pain. The blood coagulation time was 10 minutes. An exploratory operation was performed on Jan. 29th and carcinoma of the gall-bladder and liver was found. Profuse hæmorrhage took place on the night following the operation and continued until death which took place on Feb. 1st. In Case 2 a woman was admitted on Jan. 30th with jaundice of four months' duration and intermittent fever. She had multiple xanthoma. The blood coagulation time was eight minutes but under calcium chloride it was reduced to three and a quarter minutes. On March 5th numerous gall-stones were removed from the gall-bladder and common bile-duct. Hæmorrhage took place on the following day and a hæmatoma formed. On March 9th there were severe bleeding and collapse. Recovery gradually took place. In Case 3 a woman was admitted on Feb. 19th with jaundice of nearly 10 years' duration. She had had attacks of hæmorrhage, chiefly from the nose and the uterus, in two of which she nearly died. An attack was in progress and she was pulseless and blanched. The hæmoglobin was 20 per cent of the normal and the red blood corpuscles were 1,600,000 per cubic millimetre. She had multiple xanthoma. The coagulation time was 14 minutes. A month later it was four and a half minutes and the red corpuscles had risen to 4,000,000 per cubic millimetre. On March 22nd there were slight epistaxis and a few petechiæ. In consequence of the tendency to hæmorrhage, even when the coagulation time was four minutes, and her extraordinary tolerance of the jaundice, operation was not advised. Case 4 was that of a stout, healthy-looking woman who was admitted on Feb. 19th with pain, nausea, vomiting, and jaundice of four weeks' duration. The coagulation time was three and one-third minutes. Operation was proposed, but she became collapsed, had hæmatemesis, and died. The necropsy showed gall-stones, cancer of the gall-bladder, extensive hæmorrhage into the lesser peritoneum, and hæmorrhage into the stomach. In Case 5 a man who had jaundice of four years' duration was operated on. On attempting to separate adhesions about the bile-ducts he bled so profusely that the operation had to be abandoned. Professor Osler points out the importance of surgeons taking into account the tendency to bleeding in chronic jaundice. Calcium chloride in 20-grain doses thrice daily, as suggested by Professor Wright of Netley, decreases the blood coagulation time, and subcutaneous injections of gelatine may be used for the same purpose. But, as shown above, bleeding may occur when the coagulation time is normal.

THE DEGRADATION OF FOOD.

THERE can be no doubt that during the past decade food has undergone a steady degradation, and this cannot be without a demoralising influence upon the human race. It will be noticed that by far the majority of cases of tampering with food relate to the substitution of a cheaper article rather than to the addition of an injurious substance. The common defence is that modern conditions of life make substitution a necessity. It is difficult to see the logic of such a defence—at least, in a number of instances. It is urged, for instance, that jam or marmalade cannot be made without the addition of glucose which prevents the preserve from crystallising. Now long before glucose was a household word jams and marmalade were made—and very good they were, too—consisting entirely of sugar and fruit In the same way we are told that beer must be brewed from sugar and that brewing exclusively from malt presents untold difficulties. Again, golden syrup, which used formerly to be the refined syrup of molasses, consists largely now of artificial sugar, which is doubtless a more marketable product but is not the same thing as cane sugar. Yet, again, we are told that the public demand a perfectly white loaf of bread, the truth in reality being that machinery has produced a roller flour which is an inferior thing to the now, we suppose, extinct stone-milled flour. Instances of this sort could be multiplied. We could wish that all those keeping house would make up their minds seriously to return to the excellent custom of preparing many articles of food for themselves at home. Who does not admit the charm of home-made bread, home-brewed beer, or home-made jam, and simply because they are known to be made from an honest formula which has stood the test of time and from good materials which yield a palatable product? Even in the country good old-fashioned wheaten bread, with that fascinating brown colour of rich wheaten flour, containing the entire nutritious portions of the berry and possessing that delightful wheaten flavour, now seldom, if ever, characteristic of bread, is difficult to obtain. The baker's loaf is, as a rule, a tasteless, insipid article which requires a considerable appetite before the idea of eating it can be entertained. No wonder that the taste for bread is steadily diminishing, and undoubtedly less bread is consumed than used to be the case. As is well known, bread contains almost every element of food necessary for existence, but we should be sorry for the person who tried to subsist entirely upon the modern uninteresting loaf made from blanched roller mill flour. It has recently been stated that the degradation of the teeth so noticeable amongst us now is due to roller milling having largely supplanted stone milling. We should not be surprised. The degradation of food is a very serious matter and is bound to lead sooner or later to the degradation of the eater. No movement could confer greater blessing upon the people than that which aimed at bringing about a return to the older and more rational methods of preparing food. Let us see more of the home-made article than we now see; let us return to more palatable food and to food that will do more good than the machine-made stuffs and the endless series of substitutes. In all the schools throughout the land we would have the children taught the advantages of home-made food, and how that bread, fruit, jam, or even beer and cider can be made at home. It would encourage a spirit of industry, it would give us palatable and nourishing articles to eat or drink, and might have a very wholesome effect upon those who seem deliberately to attenuate food as much as possible or who pay no regard to its naturally endowed palatability.

THE very sudden death is announced, on August 2nd, of Dr. Julius St. Thomas Clarke of Leicester. It will be remembered that in October of last year Dr. Clarke was seriously assaulted by a maniac named Kirby who fired four shots from a revolver at him as he was walking in the street. Dr. Clarke was wounded in the lower part of the spine and lay in a critical state for some time, but eventually recovered, and by November was well enough to give evidence against his assailant before the magistrate, as we mentioned in THE LANCET of Nov. 10th, 1900, p. 1392.

AT a meeting of the Distribution Committee of the Metropolitan Hospital Sunday Fund, held on July 31st under the presidency of the Lord Mayor, two amounts of £706 13*s.* 4*d.* and £706 6*s.* 8*d.* for last year and this year respectively were ordered to be paid over to the National Hospital for the Paralysed and Epileptic, Queen-square, Bloomsbury, W.C. These two amounts had been held over pending the settlement of the recent disputes between the board of management and the medical staff.

DURING the week ending July 28th seven cases of plague and three deaths from the disease were reported from all Egypt; of these, four cases and three deaths occurred among natives and three cases among Europeans of Greek nationality. Four cases and one death were reported from Alexandria, two cases and one death from Zagazig, and one case and one death from Port Said.

IN the *Times* of Wednesday last appeared a long and vehement letter from Mr. Burdett-Coutts, in which he appears to be exceedingly angry with Sir W. MacCormac for having, as it was reported, said that "Mr. Burdett-Coutts had no idea of perspective and exaggerated everything." We understand that Sir W. MacCormac did not mention Mr. Burdett-Coutts's name.

HIS MAJESTY the KING has been graciously pleased to grant his patronage to the Dental Hospital of London which has recently been rebuilt in Leicester-square, London.

ASYLUM REPORTS.

Salop and Montgomery Asylum (Annual Report for 1900) —The average number of patients resident during the year was 787 and comprised 344 males and 443 females During the year 213 patients were admitted and of these 49 were not first admissions The latter does not include 11 patients who were received as transfers from other asylums Dr Arthur Strange, the medical superintendent, states in his report that from the nature of the admissions and the number of old people in the asylum the recoveries during the year were lower and the deaths were higher than the average. A falling off in the number of curable cases among the admissions has been steadily going on for some years The question of increased accommodation for patients is getting urgent, and owing to delay and uncertainty in matters jointly concerning the counties of Salop and Montgomery no progress has been made The asylum has suffered severely from an epidemic of colitis to which seven inmates, all males, have succumbed. Dr Strange believes that "while being unable to trace the origin of the disease there can be no doubt that it is infectious and that isolation and cleanliness are the best and perhaps only means of arresting its spread The appearance of this disease [colitis] in two successive years, and the occurrence of so many cases of phthisis as evidenced by the number of deaths from that affection year by year point to the need of wards where these and other similar cases can be treated separately This is simply impossible in the present building, which is generally overcrowded with acute cases' Five cases of fractured bones occurred during the year, one being a case of fractured ribs attended with a fatal result An inquest was held and a verdict of "accidental death' was returned Dr Strange regrets to have to report too numerous changes amongst the staff due to various causes He believes that a *spirit of unrest pervades the class from* which attendants are taken, especially the females "Many [illegible] up after a short time without [illegible] ial I also doubt whether the [illegible] to the level of former years One evidence of this is the number of dismissals, no less than eight, males and females, left in this manner, and four others (including one female) left without giving any notice' The deaths during the year amounted to 116 the highest number ever recorded in the asylum—viz, 58 males and 58 females, or 14·7 per cent of the average number resident Of the deaths two were due to cancer, three each to influenza, bulbar paralysis, and general paralysis, six to apoplexy, seven to colitis, nine to cardiac disease, 13 to epilepsy, 15 to phthisis, 19 to senile decay, and the rest to other causes 48 patients were discharged as recovered during the year, or 6 1 per cent of the average number resident. An outbreak of swine fever occurred which is the second since the new farm buildings were erected in 1884 It rapidly spread during February, March, and April, at the end of which time all the pigs with the exception of 51 had either died or had been slaughtered in the hope of stopping its spread The total loss of pigs was 162. The outbreak could not be traced to any infection and not even a guess could be made at its origin The Commissioners in Lunacy state in their report that special stress had been laid by them a year previously upon the need of additional asylum accommodation to meet the increasing requirements of the two counties and express their regret to be unable to report *that any definite action* has been taken, although there has been an increase in the number of patients. They report favourably on the condition of the day rooms, dormitories and bedding The notes in some of the case books are in arrear, and they think that the particulars relating to injuries sustained by patients should be given in more detail They find no provision of a room or appliances for pathological research In the absence of suitable separate accommodation cases of phthisis have to be treated in open wards The Asylum Committee state in their report that owing to the increase in the cost of maintenance the weekly charge per patient will be raised from 7*s* 9*d* to 8*s* 6*d* as from July 1st, 1901. The sum of £285 had been expended in alterations and repairs, and works for connecting the asylum sewer with the sewerage system of the borough of Shrewsbury have been sanctioned at an expenditure of £300

Western Counties Idiot Asylum, Starcross, Exeter (Annual Report for 1900) —The average number of patients resident during the year was 256 During the year 44 patients (33 boys and 11 girls) have been admitted The tendency of many boards of guardians is to send to the institution only helpless and unimprovable children (idiots or imbeciles) As the institution is an educational rather than a custodial asylum for idiots imbeciles, and the feeble minded the term "idiot asylum is rather inadequate to convey its meaning and purpose Physical training reading writing and arithmetic, and industrial occupations such as tailoring bootmaking basket making mat making and wood carving are taught in classes, while domestic work needlework knitting, and the manufacture of straw hats are specially taught to the girls Mr E R S Lipscomb, the medical officer states in his report that the institution has been exceptionally free from infectious and other diseases during the year, with the exception of influenza which attacked some of the male patients, one of whom died from it During the year there were only three other deaths all of them from pulmonary tuberculosis An epidemic of ophthalmia which had long troubled the patients has at length become extinct The Commissioners in Lunacy state that at their visit the wards and rooms were in good order and that with the exception of five patients who were ill or in bed all the rest were up and busily employed in various ways The floors of the rooms are either dry rubbed and stained, or treated with oil The principal improvements which have taken place have been the building of two new workshops with dormitories overhead and a covered corridor to connect the workshop block with the main building Steam cooking has been introduced into the kitchen The late secretary of the institution died after 25 years of service and was succeeded by his son The adjoining house Elm Court, with a large garden and two acres of land has been taken on lease The accounts for the year closed with a balance in the treasurer's hands of £305 13*s*

ROYAL COLLEGE OF SURGEONS OF ENGLAND

AN ordinary meeting of the Council was held on August 1st, the President, Mr H G HOWSE, being in the chair

A report from the Committee of Management was approved It recommended the addition of the University of Birmingham to the list of recognised universities whose examinations are accepted in lieu of the first and second examinations of the Conjoint Board The following recommendation was also adopted —

[illegible]

next

The report of the Finance Committee was received and approved The gross income of the College for the past year was £26 104 being £893 greater than in the previous year This increase was chiefly due to a continued advance in the amount of the fees paid by candidates for the diploma in dental surgery As regards the fees for the examinations of the Conjoint Examining Board there was a decrease of £133 The expenditure of the College for the past year amounted to £23.989 being £424 more than in the previous year There was a decrease of £250 in the fees paid to the examiners of the Conjoint Examining Board The expenses of the Fellowship examinations were £323 [illegible] and were £29 in excess of the fees paid by the candidates, but the revised regulations will come into force in October, 1902, and this loss will not then occur

The balance of income over expenditure amounted to £2155 but from this must be deducted a sum of £490 for one half-year's rates which had not yet been demanded.

THE
BRITISH MEDICAL ASSOCIATION
MEETING AT CHELTENHAM.

THE summer general meeting of the members of the Irish Medical Schools and Graduates' Association was held at the Ladies' College, Cheltenham, on July 31st. The attendance of members was unusually large and included Professor Alexander Macalister, F.R.S., and Dr. E. D. Mapother, vice-presidents; Sir John William Moore, Dublin; Sir William R. Kynsey, K.C.M.G., Surgeon-General C. M. Cuffe, C.B., Surgeon-General C. Sibthorpe, C.B., Professor R. J. Anderson of Galway, Professor W. H. Thompson of Belfast, Colonel J. P. H. Boileau, A.M.S., Fleet-Surgeon Gilbert Kirker, R.N., and the honorary secretaries, Mr. J. Stewart and Dr. J. H. Swanton. In the absence of the President, Dr. W. Alexander of Liverpool, the chair was occupied by Dr. Mapother. The council reported that since the last annual meeting the restrictive rule with regard to qualifications for the staff had been repealed in the case of two provincial hospitals. Sir J. W. Moore stated that the subject of the exclusion of those holding the higher diplomas of his college from candidature for honorary appointments in the English hospitals had for several years engaged the attention of the Royal College of Physicians of Ireland. After some remarks on the same subject from Professor Thompson the meeting adjourned.

The annual dinner of the British Medical Association in connexion with the meeting at Cheltenham was held on August 1st at the Cheltenham College in the big hall. The company numbered close upon 400 and the chair was taken by Dr. G. B. Ferguson, the President of the Association. The toast list was a long one and whether it was that the hall was a very difficult one for the speakers to make themselves heard in, or whether the company had so much to say to one another that they could not listen to the speakers, the fact remains that most of the speeches were delivered in dumb show. This did not interfere with the length of an inaudible oration delivered by a gallant General who took no notice of cheers, talking, or shouting, and turned a deaf ear to a bugler who was summoned especially to sound the "Cease Fire" in the hopes that that martial order would attract the speaker's attention. It was noticed that the noisy, not to say tumultuous, assembly was during the delivery of Sir W. Mac Cormac's remarks perfectly quiet. Among the names of speakers on the programme were those of Mr. G. S. Bazley, Surgeon-General J. B. Hamilton, Colonel Rogers, Inspector-General A. Turnbull, Mr. W. F. Hicks-Beach, the Rev. Canon Roxby (Rector of Cheltenham), the Mayor of Cheltenham, Sir William Broadbent, Mr. J. T. Agg-Gardner, M.P., Mr. Brandt for the Deputy Mayor, Dr. Roberts Thomson, Sir William Church, Dr. R. W. Batten (Gloucester), Dr. Sabouraud (Paris), Professor Onodi (Budapest), and Professor George Dock (Michigan). The guests did not separate till a late hour which somewhat delayed the reception given by the ladies in an adjoining hall of the College. If judged by the noise occasioned the dinner would certainly appear to have been one of the most successful ever held; the guests undoubtedly thoroughly enjoyed meeting their friends, with whom they cheerfully conversed in anything but whispers.

A meeting was held on August 2nd at the Ladies' College to discuss the question of the forthcoming election of Direct Representatives to the General Medical Council. A full report of the proceedings will be found at p. 408.

As a result of the offertory at St. Matthew's Church, Cheltenham, on the occasion of the annual sermon preached by the Dean of Gloucester before the British Medical Association a sum of £40 was collected. This offertory has been divided between the Royal Medical Benevolent College, Epsom, and the British Medical Benevolent Fund.

THE GENERAL MEETINGS.

THE THIRD GENERAL MEETING.

The third general meeting was held in the Princess Hall of the Ladies' College at Cheltenham on August 1st. The chair was taken by the President of the Association, Dr. G. B. FERGUSON. The proceedings commenced with an Address in Surgery by Sir WILLIAM THOMSON, C.B., honorary surgeon to the King in Ireland, which was published in full in THE LANCET of August 3rd, p. 264. The next item on the programme was the presentation of the Stewart Prize to Dr. Patrick Manson.

Report of Constitution Committee.

The consideration of the recommendations contained in the report was resumed.

Want of space compels us to omit the discussion on the remaining clauses of the report, but we hope to publish it in a future issue. In the meantime we may say that the report was received.

THE FOURTH GENERAL MEETING.

The fourth and concluding general meeting of the members of the British Medical Association was held on August 2nd in the Princess Hall of the Ladies' College, Cheltenham, under the chairmanship of the President, Dr. G B. FERGUSON.

The following motions received from the Section of State Medicine were duly proposed, seconded, and carried:—

1. Having regard to the paramount importance to the interests of the public health of security of tenure of office of sanitary officers, the State Medicine Section beg to express their approval of the action of the Council in promoting a Bill in Parliament to that end and their thanks for the same.

2. That, as it appears desirable in the interests of the public health to minimise opportunities for the introduction of disease by ship-borne rats, it is of im [illegible] for this purpose should be so framed a [illegible] and commerce of the country. This [illegible] the captains of vessels loading at plague-infected ports should be ordered to destroy rats on board ship before loading cargo, and to take precautions for preventing rats getting on board during the time the cargo is being loaded, and that British Consular certificates should be issued to captains obeying such orders.

The following motion from the Ophthalmological Section was duly proposed, seconded, and carried:—

That it is of opinion that the just and friendly settlement of claims for injury to the eyes under the Workmen's Compensation Act, 1897, would be greatly facilitated by a knowledge of the condition of the eyesight of the injured person before the accident, and recommends that employers should adopt some simple plan whereby a record of the sight of each eye should be appended to the name of each workman in the wage-books.

After the usual votes of thanks had been accorded Sir WALTER FOSTER, in an eloquent speech, moved a cordial vote of thanks to the President, Dr. Ferguson, for his conduct of the meetings. This was seconded by the honorary treasurer of the Association, Mr. ANDREW CLARK, and carried by acclamation.

THE SECTIONS.

MEDICINE.

THURSDAY, AUGUST 1ST.

Dr. E. S. REYNOLDS (Manchester) opened a discussion on

Peripheral Neuritis in Beer-drinkers: Its Precise Causation and Diagnosis.

He commenced by describing the now well-known outbreak of peripheral neuritis which occurred in Manchester and district in the latter part of last year. Attention was first directed to the very considerable increase in the number of cases of peripheral neuritis that were being admitted into the hospitals and Poor-law infirmaries of that locality. When these cases were studied it was found that in addition to the well-recognised symptoms which had for a long time been known as those of alcoholic neuritis others, such as pigmentation of the skin, cardiac muscle failure, and loss of memory of time and place, were also present. When this disease was first described it was supposed to occur almost exclusively among spirit-drinkers, but in this outbreak, as well as in isolated cases occurring from the year 1884 onwards, drinkers of beer were more affected A large majority of the cases seen in the autumn of 1900 had the skin pigmentation very marked, the condition of the extremities resembling that described as erythromelalgia, suffusion of the conjunctiva and nasal mucous membrane, diarrhœa, herpes, pain, and sweating in the feet and hands All these patients were beer drinkers In November arsenic was discovered to be present in several samples of beer and this, again, was traced to certain sugars used in the brewing process, which all came from the same manufactory The presence of arsenic in these was afterwards found to be due to the use of impure samples of sulphuric acid in their preparation The quantity of arsenic found in these beers varied from one-thirtieth to one and a half grains of arsenious oxide to the gallon , in the impure ingredients the same substance was present, in the case of invert sugar the amount of one grain per pound, in the glucose four grains, and in the sulphuric acid the amount of 100 grains per pound were found. The connexion between the ingestion of large quantities of arsenic and the disease in question being thus established they had to consider the following points Two views on the subject might be held first, that the symptoms were caused by the two substances acting together—e g , that the arsenic caused the effect upon the skin and that the alcohol caused the neuritis , the second theory was that all previous cases were really due to arsenic and not to alcohol In support of the latter theory peripheral neuritis had now almost entirely disappeared from Manchester, its former home There had, however, been one or two cases quite lately, but in both arsenic was found in the hair of the affected patients, and on analysing the beer they had been in the habit of drinking it was found that it contained more than a trace of arsenic Peripheral neuritis had undoubtedly occurred in persons who only drank spirits and wines, but wines were adulterated with various substances which undoubtedly contained arsenic Whisky might become contaminated with arsenic from the use of impure sulphuric acid used in cleaning the still, and an instance was related in which crystals of arsenious oxide were actually found in a still head Malt had been found adulterated with arsenic as a result of using coke in the drying processes Though no such symptoms in relation to the skin had been described by observers in the earlier cases of peripheral neuritis it was possible that these might have been overlooked There was a third possibility—i.e , that alcohol and arsenic were both able to produce all the symptoms of the disease, but that their action was intensified when they were both acting at the same time If alcohol by itself could cause peripheral neuritis it was evident from the large amount consumed that alcoholic neuritis must be the rarest disease He considered that a large number of the cases credited to alcohol were really arsenical in origin Beri-beri was a form of peripheral neuritis not confined to the tropics, but which had also occurred in certain asylums, notably in Dublin In one place where it was supposed to be endemic it affected workers in tin mines and there he considered that the cause was arsenic ; and he thought that the same cause had operated in other outbreaks of beri beri, but he would not say that that disease was invariably due to arsenic. In conclusion he showed tubes having arsenical mirrors which had been prepared from the hairs of the patients who had been seized during the last few weeks He showed a large number of lantern slides illustrating the scaling of the skin pigmentation, bullæ, purpuric spots, wasting of the interossei, wrist-drop, paralysis of the arm and leg muscles, and of the diaphragm

Professor DIXON MANN (Manchester) exhibited specimens of Arsenic Crystals from Hyperkeratosis, from the Hair and from the Nail Clippings in arsenicated beer cases He discussed the pathology of arsenical neuritis , the cases in Manchester were very severe and perhaps their most prominent symptoms were the extreme tenderness of the muscles and the disturbance of the cardiac innervation He thought that both alcohol and arsenic combined in their causation but that alcohol acted by interfering with the molecular changes in the nerve cells and so rendering them liable to be affected by the arsenic The effects seemed to some observers to be in excess of the amount of arsenic taken He saw no evidence of this He thought that very large amounts of arsenic must have been taken in some of the cases. Some of the samples of beer examined contained one and a half grains and even up to two grains per gallon, and a gallon per day was not an uncommon amount to be drunk. With regard to the action of arsenic on the nervous tissues he remarked on the affinity of the keratin tissues for arsenic ; it was found in the nails, the hair, the epithelial cells, and not only in such of those tissues as were removed from the influence of the active circulation of the blood. There was a substance called "neuro-keratin" which had a similar composition It was found in the axis cylinders and the sheath of Schwann and fibrils of the same substance traversed the nerves in every direction. There was also much neuro-keratin in the brain It was, however, very much more abundant (10 times) in the white substance than in the grey In view of this fact he obtained some brains from patients who had died from arsenical neuritis and roughly divided the white from the grey matter He then examined the two portions for arsenic, and as a result he found that in 240 grammes of white matter there were 0 8 milligrammes of arsenic, while in the same amount of grey matter there was merely a trace This was the result of one analysis The others were similar, and in all cases the white matter contained more arsenic than the grey In answer to the question as to how did the arsenic produce the neuritis he thought that the central cells were affected as well as the peripheral nerves If the taking of arsenic in beer was discontinued, for the first few days the symptoms of neuritis increased both in intensity and the area of the affected parts. He would compare its action to that of phosphorus as described by Mott, who considered that that poison acted on the nerve cells by preventing them storing up oxygen in their protoplasm

Dr A P LUFF (London) approved of Professor Mann's theory as to the action of arsenic on the nerve-cell With regard to Dr Reynolds's questions he thought there was alcoholic neuritis pure and simple but he agreed that the intense nerve pain, pigmentation, and skin eruptions were points of difference between the two forms He did not think that if these pains and eruptions had been present in the earlier described cases of alcoholic neuritis that they could have been overlooked. He also thought that if these earlier cases had been due to arsenic that substance would have been detected in the body either in the course of toxicological or other observations Nearly all the cases in Manchester appeared to have been affected by arsenic derived from the same source

Dr T N KELYNACK (Manchester) showed further slides and discussed the cases seen in Manchester The more important conclusions are shown in the following table —

Table indicating the Relative Frequency of Peripheral Neuritis in Different Parts of the Country

Hospital	Years	Total number of cases	Number of cases of peripheral neuritis	Percentage.
Royal Infirmary (Dundee)	1899-1900	9 000	9	0·1
Addenbrooke's (Cambridge)	1878-1901	9 006	25	0·23
Royal Victoria (Belfast)	1892-1899	7,823	23	0·29
London Hospital (Whitechapel)	1890-1899	47 183	202	0·42
St Thomas's Hospital (London)	1893-1898	7 656	37	0·43
St Bartholomew's Hospital (London)	1895-1896	10 009	62	0·61
Royal Infirmary (Manchester)	1892 1893	9 300	109	1 17
Royal Infirmary (Manchester)	1899	1,300	21	1·61
Royal Infirmary (Manchester) ...	1900	1 343	62	4·61
Royal Infirmary (Manchester) ...	November 1900-January 1901	336	43	12 7

Such returns clearly indicated that much of the so-called alcoholic paralysis met with in Manchester and district during recent years had really arisen from the use of arsenicated beer He thought that the effects of arsenic had been modified by the method of its administration in beer and thought that they had been accentuated by the action of the alcohol.

Professor W. OSLER (Baltimore) said that though very little wine and spirits were now taken by the upper classes in America, among the lower classes both whisky and beer were extensively consumed. Alcoholic neuritis was rare in that country, but it did occur, and the symptoms observed were identical with those which had been described in arsenical cases, with the exception of those relating to the skin and the vaso-motor functions. Keratosis, bullæ and the like were absent. For these reasons he considered that alcohol was the cause of the disease in the cases he had seen. With regard to the excessive pain, in other forms of neuritis, such as that occurring after typhoid fever the pains might be very severe.

Dr. NATHAN RAW (Liverpool) saw 212 cases during the Manchester epidemic; of these only 22 were acute. He thought the difference in severity was due to dosage, though there were more cases in women than in men, yet all the cases among the former were chronic in character, the reason being that the women usually drank a certain amount of beer regularly every day, whereas the men more often drank a very large quantity on particular occasions. He thought that all the cases in that epidemic were caused by arsenic and that alcohol intensified its action. The effects of arsenical neuritis were recovered from more rapidly and completely than those of the alcoholic form.

Dr. F. M. POPE (Leicester) had seen a good many cases in Leicester similar to those in Manchester. In all of these in which the source of the beer drunk by the patients could be ascertained it was found to have been contaminated by arsenic contained in products from the same manufactory as those which caused the Manchester cases. When such a great number of persons could take such very large quantities of alcohol without the production of a single symptom of peripheral neuritis he hesitated to accept the theory that alcohol alone could produce the disease.

Mr. F. ORMROD (Workington) related his experience of many cases which had occurred there.

Dr. R. CATON (Liverpool) had traced a few cases to lead and thought that the substance should be looked for.

Sir WILLIAM GAIRDNER (Edinburgh) said that he was unfamiliar with alcoholic paralysis previously to 1884 when he saw cases in Manchester with Dr. Ross. He considered that no case of this nature could have escaped his attention, but he thought that he had not seen more than eight or 10 cases in Glasgow since that time. In view of the large amount of alcohol consumed in that city he thought that alcohol was not the cause.

Dr. REYNOLDS replied and the PRESIDENT (Dr. E. T. WILSON) summed up.

Dr. R CATON (Liverpool) read a paper on

The Means of Arresting Acute Endocarditis.

He thought that progress had been made in understanding the endocarditis of acute rheumatism and that it would not be long before the microbial origin of the disease would be absolutely recognised; not so much progress had, however, been made in the treatment of the complaint. He described the results of his treatment in 92 cases of endocarditis arising in the course of acute rheumatism while the patient was actually in the hospital He insisted on three points. First, absolute rest in bed for at least six weeks on low diet; second, that salicylates did not do so much good to the heart as to the joints, and that such drugs as digitalis, strophanthus, &c, were on the whole injurious. Small blisters applied in succession over the præcordial area were very valuable and he discussed the action, or possible action, of these in exciting resistance to bacterial growth in the tissues of the cardiac valve. Thirdly, he gave sodium iodide with a view to promote absorption of the effused fibrinous material on the valves. He considered that in many of his cases he had quite prevented the extension of the disease and many were now still in good health after considerable periods.

Professor OSLER thought that they owed a distinct debt to Dr. Caton for his attempts to combat what was undoubtedly the most serious part of acute rheumatism. He had followed out the treatment and was sure that it was the correct one, but he regretted to say that he was afraid it could only be of advantage in a few cases. It was very desirable to obtain a subsequent history of the patients at a later stage, as frequently the ultimate damage caused to the valves only became apparent after a considerable interval.

Professor CLIFFORD ALLBUTT (Cambridge) thought it singular that they knew so little of the history of patients in after years. It would give them much assistance if they could see patients in 10 years after such attacks as had been described. He thought that while some murmurs reappeared after a patient's discharge from the hospital there were others that cleared up. He thought that Dr. Caton's treatment should certainly be carried out and suggested in addition that means should be taken to decrease the total mass of the blood.

Sir WILLIAM BROADBENT (London) thought it was a pity to stereotype forms of treatment and that that described by the reader of the paper was not so new as to merit a specific name. Treatment on the lines advocated by Dr. Caton had been well known since the days of Sibson. He agreed with Professor Allbutt that they often saw cases where murmurs which had formerly been loud had quite disappeared. It was not necessary to consider that a murmur always meant functional impairment of the heart, and if a murmur were present he would prefer a loud to a more faint one. If salicylates were to be of any use in the prevention of acute endocarditis or its arrest in the earlier stages they should not be given in the usual routine manner; 15 grains per hour should be given for six hours on two succeeding days. He thought that given in this way it was often efficacious. After a murmur had appeared the salicylates should be stopped as they could only do harm.

Sir WILLIAM GAIRDNER said that Sibson had taught years ago that patients should not get up for some considerable time after the temperature had become normal in rheumatic fever, and that on the occurrence of the slightest departure from a normal state they should be sent back to bed again.

Dr. W. EWART (London) agreed with Dr. Caton as to treatment, but thought that the cases with hardly appreciable murmurs were the most insidious and the worst. He thought that in future they would be able to treat endocarditis by anti-microbic remedies; even the malignant forms were not quite so hopeless as was formerly thought. He had had evidence in one case that although it proved fatal the heart had been undergoing a process of recovery.

Dr. SAMUEL WEST (London), who was now in the chair, said he rather deprecated attacking a question such as this by means of statistics. He preferred the personal opinion of a good clinical observer. In many cases the murmur might disappear, but that did not always mean that the disease had disappeared also. In some such cases if the patient's cardiac dulness was marked out before and several hours after he got out of bed marked evidence of dilatation of the heart could be found at the latter time, and in any such case prolonged rest in bed was absolutely necessary.

SURGERY.

THURSDAY, AUGUST 1ST.

Mr. GILBERT BARLING (Birmingham) opened the discussion on

Gastro-jejunostomy in Ulcer of the Stomach and Duodenum and Pyloric Stenosis.

He considered it was of importance to come to some conclusion as to the relative mortality of gastric ulcer; the statistics appeared to vary very widely—French surgeons placed them as high as from 50 to 20 per cent. This he thought much too high; he should feel inclined to place it at 10 per cent, or even lower. Death in these cases was commonly due to perforation, hæmorrhage, or inanition, and but rarely to consecutive cancer. He thought that the belief of French surgeons in the frequency with which cancer followed on such ulcers was exaggerated. As regards the indications for operative treatment, he first considered the symptom of hæmorrhage; acute bleeding, such as might bring the patient to the verge of death, he did not think a good case for operation, for it had been shown frequently that in such cases the source of even a violent hæmorrhage might be impossible of detection during life owing to the minuteness of the lesion. Cases of recurrent and slight hæmorrhages, he thought, specially invited successful treatment, and in this connexion he called attention to the comparative frequency with which considerable ulceration existed without bleeding being detected, but these, and those cases of slight and recurrent hæmorrhages, were marked by a chronic invalidism, a condition which demanded operative treatment if such could be safely afforded, irrespectively of the liability to mortality arising from the untended ulcer Such operative treatment could be safely rendered, and of the possible operations he considered gastro-jejunostomy preferable, it was attended with slight risk, it set the parts at rest, and was allowable even under extreme conditions He commented here on the difficulty of differentiation between the symptoms arising from a chronic gastric ulcer and a dyspepsia of the neurotic type. In the consideration of cases of stenosis of the pylorus with dilated and hypertrophied stomach (he excluded from this connexion the atonic dilatation of the organ in asthenia), he considered the use of Loreta's method of dilatation inadvisable—there was no inconsiderable risk of rupture of the gastric coats and even death therefrom, as he had himself seen , further, there was a liability to a recontraction of the pylorus The operation of election in selected cases was pyloroplasty , where there was simple stenosis it was an admirable operation, but with adhesions or such thickening as simulated malignant growth it was quite inadmissible The separation of adhesions—gastrolysis—he thought of doubtful use, they usually re formed , gastro-jejunostomy he thought promised better results As regards the latter operation he believed it to be the most frequently adopted and one most variable in its mode of performance Should suture or mechanical union simple or complex anastomosis, or should the anterior or posterior sites of implantation be adopted? As regards the first of these matters he noted that the use of mechanical means of union was first in the field and by their simplicity greatly popularised the operation Now sutures were pre eminent. Personally, he now used double rows of continuous sutures, but he thought the decision lay in individual skill in manipulation and in the state of the patient at the time of the operation As regards the mortality arising out of the operation, he thought that 20 per cent would well cover it, but that with some surgeons it was as low as from 10 to 5 per cent With recovery the results were as a rule excellent, but he should like some consideration as to the possibility of reducing the anxiety too often exhibited by the patient during the first few days after operation—a condition due doubtless to regurgitation of intestinal contents into the stomach

Mr GEORGE HEATON (Birmingham) stated his belief that the mortality from gastric ulcer was even less than 10 per cent , 6, 5, or even 4 per cent might be more correct. He was not sanguine of the use of operation in cases of hæmorrhage In distension of the stomach following stenosis its triumph was marked. He would add one other case as indicative of operation to Mr Barling's list, that of hour glass constriction of the stomach due to the healing of old ulcers He agreed to the inadvisability of Loreta's method and favoured gastro jejunostomy in general and pyloroplasty for special cases In gastro-jejunostomy the posterior union was theoretically the more correct, as the union would be in the most dependent spot when at rest in bed but the anterior position was the easier and surer to work at and so gave less liability to mortality He favoured the use of the button, it was quick in application and there was lessened shock. There was less liability to contraction of the new orifice with the use of the button than with suture. He strongly deprecated the use of the cheap and nasty foreign made buttons now on the market. In some
cases he had
tion into the
plane He al
jejunostomy in cases of pyloric cancer

Mr L. A. BIDWELL (London) thought there was truth in the idea of French surgeons that increased secretion of hydrochloric acid produced spasm of the pylorus and that there was such increase of hydrochloric acid in gastric ulcer , in such cases, and especially in the poor who could not afford to rest or follow dietetic measures, operation was indicated. He was sorry to hear the strictures passed on Loreta's method , his experience was not extensive, but he had one case in which there had been no recurrence after eight years The modified method—that of dilating through the invaginated stomach—was useful in slight contractions probably from spasm In pyloroplasty he had good results ; in one case there was recurrence of gastric dilatation after one year owing to the forming of adhesions at the scar , these he removed and covered the area with a flap of parietal peritoneum In gastro jejunostomy he now used the anterior method, it was easier, there was better chance of making a water-tight connexion, and so it was safer He did not like the button—he could not conceive anything worse for an ulcerated stomach than the presence of a mobile button within its cavity

Dr SINCLAIR WHITE (Sheffield) agreed that in a very limited sense pyloroplasty was the operation of election, but no adhesions must be present Gastro jejunostomy always met one's requirements, for two healthy sites for union could be selected He pointed out that Loreta was not the first to act directly on the pylorus , Rydygier had a year previously performed pylorectomy In gastro jejunostomy he preferred the anterior implantation. but thought the point strained , all that was required was a water-tight joint , this could be best effected anteriorly He preferred the suture, but confessed that in his hands the button saved 25 minutes in the operation.

Mr C A MORTON (Bristol) narrated a case in which by the operation of gastro-jejunostomy he had been able to secure comfort and well-being for a man, aged 42 years, who for seven years had been in a state of miserable invalidism

Mr J RUTHERFORD MORISON (Newcastle on-Tyne) said one cause of mortality in these cases had been overlooked, one that was dramatic in its suddenness—syncope, the patient just dropped out He did 22 consecutive operations of pyloroplasty without death, yet he acknowledged this was a matter of luck, for two cases as good in appearance as any of the others died from this cause the night preceding the day fixed for operation , and of two cases of successful gastro jejunostomy one, when apparently well, dropped dead He regarded operations in hæmorrhage as unsatisfactory, for he had seen apparently hopeless cases of hæmorrhage recover without operation , and in a case where he opened the stomach of a young woman for such symptoms nothing could be found either by touch or sight The patient died There were found two small ulcers on the anterior wall of the cardiac orifice in a position which could not be reached , one of these had perforated. He, like Mr Barling, had operated with the expectation of finding gall stones and found an ulcer in the region of the pylorus He thought that such ulcers were not sufficient to cause constriction of the pylorus and dilatation of the stomach but that owing to the difficulty of driving the food over the ulcer surface the muscle coats became hypertrophied and irregular in their action He thought adhesions of no moment, save as indications of disease within the viscus , he had always found the two concurrent He animadverted on dilatation through the invaginated gastric wall , if dilatation was indicated it should be done properly through an opened stomach , the risk of the opening was very slight His experience of gastro-jejunostomy was not good , he had tried the simple method of anastomosis and one in which he made a new S shaped duodenum out of the jejunum, to which was attached the old duodenum as a sort of bile duct , this method, indeed avoided regurgitation, but the mortality was still 50 per cent.

Mr J PAUL BUSH (Bristol) had tried posterior gastro-jejunostomy with success but agreed that it was a longer and more difficult procedure than by the anterior anastomosis

Mr R H PARRY (Glasgow) said was it not bad to cut bands of adhesion and at the same time leave masses of thickened tissue in the walls of an organ? He felt that there should be some operation intermediary between pyloroplasty and gastro jejunostomy, yet not pylorectomy He had in one case extirpated the gall bladder and excised thickened areas from the pylorus with the best results

Dr G B FERGUSON (Cheltenham) President of the Association read a paper on

An Operation for Perforated Gastric Ulcer and Three Similar Cases occurring in Gloucestershire.

His case was a classical one with the special point that the condition was at once recognised and was operated on within three hours The perforation was on the posterior surface and was closed with two rows of Lembert sutures No general washing out was practised, the abdominal cavity being merely sponged The patient a woman aged 25 years was nourished entirely by enemata for 14 days and made an uneventful recovery Dr Ferguson then detailed three similar cases operated on in his shire—one successful and two unsuccessful He gave a very complete *resumé* of the statistics and history of such operations, and found that from 110 published cases noted by him there was yielded the excellent result of 41 recoveries He strongly insisted upon the necessity of an early recognition of the condition and immediate operation and remarked that the life of the sufferer depended more upon the one into whose hands the case first came than upon the operator.

Dr. J. MURPHY (Sunderland) further emphasised the urgency of such cases and showed by the citation of some cases how the promptness of an ordinary 'busman in bringing in a patient, was more to the point than the dallying of a practitioner of medicine.

Mr. D'ARCY POWER (London) remarked on the frequency with which he had seen such cases of late and asked if there was any general feeling that there was an increase of the disease.

Mr. BARLING replied to a few points of the discussion and stated that he thought Mr. D'Arcy Power's experience was one of those curious irregularities in the law of averages such as they must have each one experienced at some time or other.

Mr. J. RUTHERFORD MORISON (Newcastle-on-Tyne) read a paper on

The After-history of a Series of Cases of Pyloroplasty for Gastric Ulcer and Pyloric Stenosis.

He said that in his experience pyloroplasty had been the most satisfactory operation in abdominal surgery. Taking into consideration the feeble condition of the patients, the mortality of the operation had been less than that of any other, and the results, immediate and remote, were equally successful. By pyloroplasty he did not mean any text-book operation, but any plastic interference with the pylorus. He had made careful inquiry as to the present condition of his first 20 cases operated upon. The first was done six years and eight months ago and the last two years ago. These inquiries showed that 14 of the patients were now in good health and took ordinary food; one could not be found but was well when last heard of; two were dead; and three, though much improved, still had occasional stomach trouble. Of the deaths one occurred about 18 months after operation from cancer of the stomach commencing at the site of operation—a malignant had been mistaken for a fibrous stricture of the pylorus. The second died from phthisis pulmonalis 27 months after pyloroplasty for cicatricial stricture of the pylorus; until the commencement of his last illness he had been well and free from stomach troubles. None had had a return of the symptoms and signs due to pyloric stricture. These results, he said, seemed to justify his belief that pyloroplasty was the operation of selection for simple pyloric stricture and that gastro-jejunostomy should be reserved for cases in which the pylorus was so bound down or involved in adhesions as to be inaccessible. A detailed table of the cases was shown.

Mr. BARLING remarked on the great usefulness of such a paper, since it was of the utmost importance to trace the after-histories of such cases.

Dr. G. T. BEATSON (Edinburgh) read a paper on

The Treatment of Cancer of the Breast by Oöphorectomy and Thyroid Extract.

He said he brought this matter forward to open discussion on the experience gained during the five years since the procedure was described in THE LANCET.[1] He gave an account of a case which he thought exemplified the beneficial effects of the treatment in a remarkable manner, for within a period of six months a large cancerous mamma had entirely atrophied and the extensive glandular enlargement present before the operation had disappeared. He made mention of what Mr. Watson Cheyne had called this "striking" control of the course of carcinoma of the female breast by oöphorectomy and thyroid feeding, as furnished by other surgeons. He raised the question of the possible explanation of such results, especially in the light of those cases of apparently spontaneous disappearance or quiescence of mammary carcinoma. Cases where improvement resulted from oöphorectomy he thought might bear on the etiology of the disease, since he regarded the apparent controlling influence of the ovaries as inimical to the parasitic theory of the disease. There arose further the big question, Did these results justify the adoption of such treatment as a primary method in the early stages of the disease? In concluding, he affirmed his confidence in the utility of the combined oöphorectomy and thyroid feeding in cases where direct operation on the disease was impossible.

Mr. BARLING said he had not done the operation and he was of opinion that the time had not come for the substitution of such a method for the recognised measures; he thought the special influence of ovarian removal on the disease not proven.

Mr. MCADAM ECCLES (London) had so treated certa cases last year with a measure of success. He asked if there was any use in the operation in cases of mediastinal growth. He believed the conjoined direct and indirect measures had a future, but was of opinion that removal of the ovaries after the menopause was useless, but as late as 39 years he had seen good effects.

Mr. H. J. STILES (Edinburgh) thought the operation was likely to be adopted even for early stages of the disease, but at present not as a routine except in far gone cases.

Mr. RUTHERFORD MORISON stated that he had had some success with the method but he must quote two cases in which the results were antagonistic. The first case was that of a woman operated upon 25 years before death; the notes of the operation by the operating surgeon had been lost, but the woman stated that both her ovaries were removed; whereas before the operation she menstruated and bore children, since, she had neither menstruated nor conceived. She died from carcinoma of the breast. The second case was one of double ovarian cysts; the glands were removed and the patient died five years later from cancer of the breast.

PSYCHOLOGICAL MEDICINE.

WEDNESDAY, JULY 31ST.

The Rôle of Toxic Action in the Pathogenesis of Insanity.

The discussion on this subject, which was opened by Dr. W. FORD ROBERTSON in a speech which we reported last week (p. 337), was continued by Dr. ROBERT JONES (Claybury Asylum) who said that he regarded the views enunciated by Dr. Robertson as too exclusively materialistic. He was himself inclined to look upon mental processes as not entirely of material nature and essence, but he regarded the relation of mind and body as a parallelism. He was inclined to look upon many of the changes in the alimentary canal as secondary to, and consequent upon, pre-existing general paralysis rather than as a cause of the disease.

Dr. EDWIN GOODALL (Joint County Asylum, Carmarthen) cited instances of puerperal insanity of toxic origin and arising from the presence of streptococcal infection and pointed out that such cases had been successfully treated by the injection of anti-streptococcic serum. The action of such a disease as erysipelas in arresting, as it sometimes did, acute insanity was inexplicable, though the fact was undoubted. He looked upon general paralysis as complicated with two sorts of toxic agencies—viz., exogenous toxic action arising from alcohol, syphilis, and the like, and endogenous intoxications following upon lesions in the inner coat of the alimentary canal.

Dr. EDWIN S. PASMORE (Banstead Asylum) referred to phthisis as a cause of insanity. The toxins of phthisis produced various forms of mental disturbance. He pointed out that experiments made in Professor Pasteur's laboratory in Paris had shown that loose ligature of the base of the appendix vermiformis was followed by a profuse multiplication of the bacillus coli communis within its cavity and a secondary local peritonitis arose therefrom. It was quite possible that the small intestine in general paralysis might be the seat of unknown (? vascular) disturbances which might be followed by an abnormal multiplication of the intestinal bacteria producing in its turn a degree of toxæmia which would act prejudicially on the brain. Such an event would serve to aggravate an already established general paralysis, but he did not believe that general paralysis was the secondary result of auto-toxæmia from the alimentary canal.

The PRESIDENT (Dr. J. B. SPENCE) thought that the swing of the pendulum was again on the turn and that the treatment adopted by their forefathers of giving blue pill and black draught might once more become popular in the treatment of insanity, as it had in other diseases.

Dr. ROBERTSON, in replying to the questions raised during the discussion, reiterated his conviction of the importance of toxic changes in the alimentary canal as productive factors of insanity.

Dr. A. T. SCHOFIELD (London) read a paper on

Some Conditions of Success in the Treatment of Neurasthenia.

He used the word "neurasthenia" in the broadest sense and included hysteria in it. He regarded the personality of the physician as an important factor in successful treatment, the qualities needed being sympathy, patience and perseverance, firmness, tact, and honesty towards his patient. The physician should realise in regard to hysterical patients the significance of the dictum that "diseases of the imagination are not imaginary diseases." Hysteria and neuromimesis both arose from a disorder of the "sub conscious mind." In neurasthenia the exciting cause arose *ab extra*. The patient might already have been treated by various local practitioners before he consulted the alienist or nerve specialist and the latter should not "pooh pooh" the symptoms as trivial or imaginary, because that would provoke distrust in the patient's belief of the physician's power of cure and thus retard recovery. Sexual excesses, both natural and unnatural, should be carefully inquired into and treated in neurasthenic cases. The treatment should be varied to suit the patient and not *vice versa*. The attitude of the physician should, on the whole, be dogmatic and weighty, the nurse placed in charge of the patient should be docile and unaggressive, one of a type intermediate between the hospital and asylum nurse. The patient should be treated in a "home" or special institution where the dietary could be varied exactly in conformity with medical orders. Grounds for open-air exercise must be open to the patients. Neurasthenics required rest, with a little massage and some degree of over-feeding. Hypnotism was of doubtful value. Electricity was better by reason of its direct action on the tissues and indirectly by the "mental suggestion" which was aroused in the patient. Rest in bed might be bad *in certain mental cases with a tendency to fixed delusions*. Introspection should be discouraged in such patients and diversions were necessary to do so. Any degree of restlessness, insomnia, dyspepsia, or constipation which might be present should be suitably treated. After convalescence the patient should not return to his old life and surroundings, but a different kind of life and occupation should be chosen. Cycling and golfing were powerful therapeutic aids to treatment.

---

[1] THE LANCET, July 11th, 1896, p. 104.

In the discussion following the above paper,

The PRESIDENT emphasised the proposition that the physician in charge of neurasthenic and hysterical cases should be kind, sympathetic, tactful, and firm towards his patient and said that Dr. Schofield's paper was of especial interest to those who in our asylums had to treat acute mental disorders allied to neurasthenia and hysteria.

Dr. FLETCHER BEACH (London) said that sympathy on the part of the physician was a *sine quâ non* in successful treatment, the patient being more in need of sympathy than of medicine. The patient's symptoms were not to be scoffed at, because that made him lose heart and confidence in the physician. Perseverance and tact were also of importance. Attention to detail was a point of practical importance—e.g., to plan out for each day the details regarding diet, sleep, and occupation for the patient. This removed the patient's mind from morbid introspection. A nursing home and the Weir Mitchell treatment were costly, but open-air treatment (exercise and sitting out of doors) was cheap and included the advantages of sunlight. Hypnotism was not so successful as treatment of the gastro-intestinal tract in order to correct auto-intoxication.

Dr. F. W. EDRIDGE GREEN (Hendon) thought that hysteria and neurasthenia blended and that sometimes they merged into delusional insanity with "fixed ideas." Thus, one patient mentioned by him had the idea that constipation was beneficial, and she thus did all in her power to avoid action of the bowels.

Dr. JONES inquired whether post-influenzal mental cases were more frequently of the exalted or of the depressed type and questioned the value of stimulants because in some cases he had known patients to lapse into habits of intemperance.

Dr. SCHOFIELD, in replying, stated that the long neglect by physicians of the psychology of the sub-conscious mind was one cause of backwardness in therapeutic knowledge. Hysterical and neurasthenic patients were not malingerers as a rule. Post-influenzal psychoses were sometimes of a melancholic and sometimes of a delusional type, and markedly obstinate to treatment. Stimulants should be given only after ascertaining the previous habits of the patient.

Dr. GOODALL read a paper on

The Anthropometrical Examination of Asylum Patients

with a scheme for the same. He pointed out that the United States and Italy were far ahead of us in this respect. He suggested a scheme for anthropological measurements of the head, face, body, and limbs, and exhibited callipers and goniometers for measuring lengths and angles. The variations in 28 normal subjects as regards measurements on the two sides of the body showed that little asymmetry existed, but marked asymmetry existed in the insane.

The PRESIDENT and Dr. JONES made a few appreciative remarks and suggested that Dr. Goodall should draw up a scheme for asylums so that others could coöperate in making anthropometrical observations on the insane.

ANATOMY AND PHYSIOLOGY

WEDNESDAY, JULY 31ST.

After Professor MACALISTER'S opening address a discussion took place on

The Topographical Anatomy of the Thoracic and Abdominal Viscera from a Systematic and Clinical Standpoint.

Professor CHRISTOPHER ADDISON (Sheffield) was followed by Dr. E. C. CARTER (Cheltenham) and other speakers.

Mr. T. S. ELLIS (Gloucester) then read a paper on the Physiology of the Lower Limb and the Military March, and this was followed by a paper read by Mr. E. H. VAN SOMEREN (Venice) entitled

Was Luigi Cornaro Right?

He said: Being a young and obscure general practitioner, it is with some trepidation and an apology that I present myself before this section. The reasons for my doing so are: First, that I believe that a hitherto unsuspected reflex in deglutition has come to light, which has an important bearing on health, the prevention of disease, and metabolism. Secondly, that any theory whatever based on a possible *physiological function claiming to diminish*, as this does, the amount of sickness and suffering now existent, should have serious investigation. Thirdly, that I desire to enlist your skilled help in the consideration of the theories I have doubtless crudely erected on my premiss. According to the "Encyclopædia Britannica," "Luigi Cornaro (1467–1566) was a Venetian nobleman famous for his treatises on a temperate life. From some dishonesty on the part of his relatives he was deprived of his rank and induced to retire to Padua where he acquired the experience in regard to food and regimen which he has detailed in his work. In his youth he lived freely, but after a severe illness at the age of 40 he began under medical advice gradually to reduce his diet. For some time he restricted himself to a daily allowance of 12 ounces of solid food and 14 ounces of wine. Later in life he still further reduced his bill of fare and he found that he could support his life and strength with no more solid meat than an egg a day. So much habituated did he become to this simple diet that when he was above 70 years of age the addition by way of experiment of two ounces a day had nearly proved fatal. At the age of 83 he wrote his treatise on the 'Sure and Certain Method of Attaining a *Long and Healthful Life*.' And this work was followed by three others on the same subject composed at the ages of 86, 91, and 95 respectively. 'They are written,' says Addison,[1] 'with such a spirit of cheerfulness, religion, and good sense as are the natural concomitants of temperance and sobriety.' He died at the age of 98." Some say at the age of 103. Now, was Luigi Cornaro right? Did he make use of a physiological process unknown to us of the value of which he was not cognisant? To live to an advanced age must we be as temperate as he, reducing the quantity of our food to a minimum required by nature? That we all eat more than we can assimilate is unquestionable. How can we determine the right quantity? Instinct *should* guide us, but an abnormal appetite often leads us astray. Nature's plans are perfect if her laws are obeyed. Disease follows disobedience. Wherein do we disobey? We live not upon what we eat but upon what we digest. Then why should undigested food, recognisable as such, be deemed a normal constituent of our solid egesta? Something like the following must be a common experience to general practitioners, especially to those practising on the continent. The patient comes to see us and volunteers the information that he or she has "the gout," "rheumatic gout," or "dyspepsia." Symptoms are asked for. The case is gone into carefully for causation. An appropriate diet and an appropriate bottle of medicine are prescribed. As the patient leaves the room we may or may not call attention to the fact that both teeth and saliva are meant to be used. The patient returns better, *in statu quo*, or worse.

---

[1] Spectator, No. 195.

If better he remains so while under treatment and relapses when he returns to ordinary habits. If unaffected or worse we try again and again until we despair, then take him, or send him, to a consultant. Temporary benefit, possibly owing to renewed hope, results, but finally the unfortunate patient gets used to his suffering, and, if he can afford it, is sent to join the innumerable hosts that wander from one *Bad* to another, all Europe over, trying, praising, and damning each in turn. Their manner of living is, of course, at fault. Nature never intended that man should be perpetually on a special diet and hugging a bottle of medicine, nor did she ordain that he should go wandering over Europe drinking purgative and other waters.

Though early yet to speak with certain voice, it would seem that we are provided with a guard, reliance on which protects us from the results of malnutrition. There seems to be placed in the fauces and the back of the mouth a monitor to warn us what we ought to swallow and when we ought to swallow it. The good offices of this monitor we have suppressed by habits of too rapid eating, acquired in infancy or youth. Last November my attention was called by Mr. Horace Fletcher, an American author living in Venice, to the discovery in himself of a curious inability to swallow, and a closing of the throat against food unless it had been completed masticated. My informant stated that he noticed this peculiarity after he had begun excessively to insalivate his food, both liquid and solid, until all its original taste had been removed from it. Any tasteless residue in the mouth, being refused by the fauces, required a *forced* muscular effort to swallow. He further told me that since adopting this method of eating he had been cured of two maladies, adjudged chronic, the suffering from which rendered him ineligible for life insurance. His weight now became reduced from 205 pounds to 165 pounds. He had practised no abstemiousness, had indulged his appetite, both as to selection and to quantity, without restraint, and for the last three years had enjoyed perfect health. After his cure he was accepted without difficulty for insurance, the last examination finding him an unusually healthy subject for his age. Having leisure he had spent three years in investigating the cause of his cure, had pursued experiments upon others and had extended his inquiries both in America and Europe, until our meeting in Venice. He had also published a statement and inquiry in book form entitled "Glutton or Epicure," which has been reviewed by THE LANCET.[2]

For nearly a year I also had been experimenting on myself and others with various diets and was ready to believe that in the manner of taking food and not altogether in its varying matter lay perhaps its protean effects on our systems. I at once adopted the same method of eating. At the end of six weeks I noticed that not only did the fauces refuse to allow of the passage of imperfectly prepared food, but that such food was returned from the back to the front of the mouth by an involuntary, though eventually controllable, muscular effort taking place in the reverse direction to that occurring at the inception of deglutition. What actually happens is this: Food as it is masticated slowly passes to the back of the mouth and collects in the glosso-epiglottidean folds, where it remains in contact with the mucous membrane containing the sensory end-organs of taste. If it be properly reduced by the saliva it is allowed to pass the fauces, a truly involuntary act of deglutition occurring. Let the food, however, be too rapidly passed back to these folds—i.e., before complete reduction takes place—and the reflex muscular movement above referred to occurs. The process of this reflex is as follows. The tip of the tongue is involuntarily fixed at the backs and bases of the lower central incisor teeth by the anterior fibres of the genio-hyoglossi muscles. With this fixed point as fulcrum, the lower and middle fibres of these muscles, aided by those of the stylohyoid and styloglossi muscles, raise the hyoid bone, straighten out the glosso-epiglottidean folds, passing their contents forwards by the fauces, the opening of which is closed by approximation of its pillars and contraction of the superior constrictor. The tongue, arched postero-anteriorly by the genio-hyoglossi, palato- and styloglossi muscles, laterally, by its own intrinsic muscles, is approximated to the fauces, soft and hard palates in turn, and thus the late contents of the glosso-epiglottidean folds are returned to the front of the mouth for further reduction by the saliva preparatory to deglutition. The word "reduction" is used for the reason that all foods tested are found, without exception, to give an acid reaction to litmus when served at table. The reflex muscular movement occurs in the writer's case from five to 10 times during the mastication of each mouthful of food according to its quantity and its degree of sapidity. As often as it recurs the returned food continues to give an acid reaction, while food allowed to pass the fauces is alkaline. Saliva flowing in response to the stimulation of taste seems more alkaline than that secreted in answer to mechanical tasteless stimulation. It is found that the removal of original taste from any given bolus of food coincides with cessation of salivary flow and complete alkaline reduction The fibre of meat, gristle, connective tissue, the husk of coarse bread, and cellulose of vegetables are carefully separated by the tongue and buccal muscles and rejected by the fauces. To swallow any of these necessitates a forced muscular effort which is abnormal. Adult man was not originally intended to take his nourishment in a liquid form, consequently all liquids having taste, such as soup, milk, tea, coffee, cocoa, and the various forms of alcohol, must be treated as sapid solids and insalivated by holding them in the mouth, moving the tongue gently with straight up-and-down masticatory movement until their taste be removed. Water, not having taste, needs no insalivation and is readily accepted by the fauces.

In explanation of the phenomenon described, the following theory is advanced. That the fauces, back of the tongue, epiglottis, in short, those mucous surfaces in which are placed the sensory end-organs of taste and "taste-buds" (the distribution of which, by the way, has yet to be explained), are the surfaces which, readily becoming accustomed to an alkaline contact by excessive insalivation and consequent complete alkaline reduction of the food, afterwards resent an acid contact and express their resentment by throwing off the cause of offence by the muscles underlying them. This phenomenon must not be confused with the cases of rumination and regurgitation which from time to time are recorded. The food in this case is not swallowed, nor does it pass any point from which it can be regurgitated. Eighty-one individuals of different nationalities and from several classes of society whom I have studied are now in conscious possession of their reflexes. These seem readily educated back to normal functions by those who seriously and patiently adopt the habit of what seems only at first to be excessive insalivation. The dictum "bite your food well" that we so often use has no meaning to those suffering from the results of mal-assimilation and mal-nutrition, especially should they have few or no teeth of their own. I make so bold as to state that dyspepsia *et morbi hujus generis omnis* will cease to exist if patients be persuaded to bite their food until its original taste disappears, and it is carried away by involuntary deglutition. The important point of the whole question seems to be this alkaline reduction of acid food before it passes on to meet subsequent digestive processes elsewhere which then become alternately acid and alkaline. In the first few months of infant life, when saliva is not secreted, Nature ordains that mammary secretion should be alkaline. With the eruption of teeth come an abundant flow of saliva and a synchronous infantile capacity for managing other foods. This flow of saliva depends on a thorough demand and use, to maintain its generous supply. It is just at this time that children learn to bolt their food, the demand fails, with a consequent detriment to the salivary glands, digestive processes, and the system generally.

A, B, C, and D were placed on an absolute milk diet: A drank his milk in the ordinary way and at the end of three days begged to discontinue the experiment owing to disgust at the monotony of the diet. B, C, and D continued the experiment for 17 days, insalivating the milk, but to a varying degree, B the least and D the most. Though D took most milk he excreted least solid egesta, C excreting less than B. Can one infer that increased insalivation of a non-starchy food ensures its better digestion and assimilation? Each subject took as much milk only as his appetite demanded, D taking the most, which never exceeded two litres daily. The weights of the subjects after the usual sudden drop of the first three days, remained remarkably even until the end of the experiment. B, C, and D all relished the diet and it satisfied the requirements of their appetites, but they experienced an increasing monotony.

As long ago as the seventeenth century, before the transformation of matter into energy by the animal organism known as metabolism was understood, the fact was recognised that by the lungs, kidneys, skin, and intestines, substances no longer useful to the organism were eliminated, the retention of which would prove harmful The nature of these substances was unknown, but it was noted that however much the food was increased the weight of the body remained the same In other words a state of complete nutritive equilibrium was maintained The following table contains the *résumé* of two experiments in which a state of complete nutritive equilibrium was maintained by individuals of about the same weight, on widely different quantities of food similar in quality The subjects of the experiments were a laboratory assistant of Dr Snyder of the United States Department of Agriculture and the writer The experiment of the former was made primarily to show the relative digestibility of the several articles of diet—potatoes eggs milk, and cream —

---

[2] THE LANCET, Oct. 13th, 1900, p. 1079.

—	Dr Snyder's experiment Published in Bulletin 43	Writer's experiment
Age of subject	22 years	30 years
Duration of experiment ..	4½ days	5 days
Number of meals	13	10
Weight at beginning	62 5 kilos	57 3 kilos
end	62·6 ,,	57 5
Potatoes (daily average)	1587 6 grammes	159 4 grammes
Eggs	411 08	124 7
Milk	710 c c	710 c c
Cream	237	237
Daily urine	1108 grammes	1098 grammes
Daily fæces	204	18·9

The daily diet of Dr Snyder's subject consisted of three and a half pounds of potatoes eight eggs one and a half pints of milk and half a pint of cream, the writer's diet of 12 ounces of solid food (like Luigi Cornaro's) consisting of three eggs and the remainder of the 12 ounces in potatoes and an equal quantity of similar liquid food to that taken by Dr Snyder's subject. The exercise of the laboratory assistant comprised his daily routine of laboratory work while that of the writer consisted of six sets of tennis or one and a half hours on horseback, with from an hour to an hour and a half's walk or climb daily, in addition to much reading and writing In each case complete nutritive equilibrium was maintained although the writer subsisted on three seventeenths of the solid food taken by the other subject.

Again cannot one infer that better assimilation and less waste resulted from the better preparation of the smaller quantity of food by insalivation? Surely, too there must be less daily strain on the intestinal canal and body generally in getting rid of 18·9 grammes of inoffensive dry waste than in getting rid of 204 grammes of humid, decomposing and offensive matter

'Considerable importance has been attached to the normal action of the bacteria in the intestines, and it has even been supposed that the presence of bacteria is essential to life. Such a view has recently been shown to be erroneous by an elaborate and painstaking research carried out by Nuttall and Thierfelder who obtained ripe fœtal guinea pigs by means of Cæsarean section carried out under strict antiseptic precautions. They introduced the animals immediately into an aseptic chamber through which a current of filtered air was aspirated and fed them hourly on sterilised milk day and night for over eight days The animals lived and throve and increased as much in weight as healthy normal animals subjected to a similar diet for the purpose of controlling the results Microscopical examination at the end of the experiment showed that the alimentary canal contained no bacteria of any kind nor could cultures of any kind be obtained from it.' "The same authors in a subsequent paper described the extension of their research to vegetable food this also was digested in the absence of bacteria. Under such conditions cellulose was not attacked Hence they consider that the chief function of this material is to give bulk and proper consistency to the food so as to suit the conditions of herbivorous digestion '[3]

Now, inasmuch as bacterial digestion has no place in the animal economy, surely it can only occur at the expense of the organism? Can micro-organic action take place in the intestines without the production of toxins and the consequent absorption of these toxins into the blood? We know that the metabolism of a cell is determined by the general physical environment of the whole organism by supplies of oxygen and water on nervous impulses and, what chiefly concerns this argument on the nature and amount of the pabulum supplied to it This pabulum is derived from the alimentary canal Are not even those of us who may be enjoying seemingly the best of health supplying to our tissues pabulum containing mild toxins, thus causing an increased katabolic action to occur in each individual cell of our bodies? Are not the blood elements floating in a plasma containing such toxins rendered less resistant weaker, less capable of fulfilling their functions as carriers and combatants of disease? Are not their and our lives in consequence more painful and shorter than they need be? Would not the elimination of these toxins render us less liable to disease? And is not their presence an important element in predisposition to disease? When this reflex is restored micro organisms get no further than the stomach They are destroyed there by the acid gastric juices then only stimulated to their full and normal secretion by the presence of a sufficiency of alkaline substance Undigested matter having been eliminated micro-organisms still existing in the intestines deprived of their means of subsistence decrease and in time may cease to exist The body no longer absorbs the toxins these produced To this fact may be ascribed the increase of mental energy, the general physical betterment the cessation of morbid cravings for food and drink, and of those of a sexual nature which are noticed and experienced

What has just been stated is based not entirely on experimental evidence but somewhat upon inference The inference seems justified because the excreta more especially of the intestines, but also of the kidneys and skin become almost odourless and entirely inoffensive The solid egesta are voided thickly covered with mucus leaving the end of the bowel dry and clean The sense of cleanliness can only then be appreciated to the full for it is internal as well as external. Flatus is no longer produced The urine is inoffensive and seems to be materially changed in quality as shown by chemical analysis Uric acid the chlorides and more markedly aromatic sulphates are reduced in quantity Owing to the deliberation in eating necessitated by this new habit satiety occurs on the ingestion of considerably less food By carefully studying one's self I believe it possible to cultivate an instinct which will regulate not only the quantity but the quality of food that the body may need and that in the normal health of a full grown body no more food either in quantity or quality should be supplied than suffices to supply diurnal waste Any excess must result in pathological processes Although there results enhanced pleasure in the taking of all foods rich and simple and especially in the appreciation of good wine the quantities of these foods and beverages that suffice fully to satisfy the appetite is much smaller than before while there is a marked preference for the simpler kinds of foods The writer now can imagine no more pleasurable meal than one consisting of good brown bread, eggs butter cheese and cream These with fresh vegetables and a very little fruit form his staple diet This tendency and preference for simple foods is the general experience among those who have recovered the reflexes of deglutition. Following on the ingestion of a lessened quantity of food and on its better assimilation there is less waste—the egesta are voided less frequently sometimes only once in from five to eight days The lower bowel is not the reservoir it formerly was So hæmorrhoids cease from troubling and constipation cannot exist For this same reason the body at the beginning of the practice commences to approximate to its normal weight increasing or decreasing as the individual's environment demands.

A few more words only need be said It has been easy to state the results of experiments and observations, but the acquiring of this new reflex while pursuing daily occupations, is not easy and needs more than a little patience and more serious thought The habits of a life time cannot be changed in a few days or weeks. The shortest time in which the reflex has been re-established is four weeks and this only by avoiding conversation at meal time and concentrating the attention on keeping the food in the mouth until complete alkaline reduction has taken place and sapidity has disappeared

In closing I wish to maintain as a fact, gentlemen of the truth of which you will only be convinced by actual experience, that by the restoration of this reflex and in complete dependence on its use, there lies true health, the establishment of a condition of staple nutrition and the possible abrogation of two great predisposing factors of disease—mal-assimilation and mal-nutrition. Unless there be among you, as in the cities of the plain, a parlous minority who possess this reflex and take their food as they ought, none of you are in the enjoyment of such health as you might have. A like punishment will be meted out to you as was visited on those cities, for you will all be consumed long before your day by the unnecessary combustion in your bodies caused by the circulation in them of toxins, the product of undigested or decomposing food. The writer, bearing in mind the warning suggested by the Frenchman, whose donkey died as soon as he had reduced his food to a single wisp of straw, finds that he is taking less and less food. While his mind is open as to his arriving at the final diet of Luigi Cornaro, yet it is easily conceivable that living a similar life of retirement in a placid environment it would be quite possible to do as he did. Hence the title of this paper and the queries at the commencement.

[3] Schäfer's Text-book of Physiology, vol. i., p 465.

This paper proved of such interest that the discussion was continued beyond the usual time.

THURSDAY, AUGUST 1ST.

The proceedings in the section opened with the reading of a paper by Dr. R. J. ANDERSON, Professor of Natural History, Mineralogy, and Geology, Queen's College, Galway, on

Rotation of the Forearm.

Professor Anderson pointed out how exceedingly complicated the motions at the elbow-joint were and how, contrary to the sometime universally received opinion, the ulna did exhibit a certain amount of movement in rotation.

The PRESIDENT and Mr. T. S. ELLIS (Gloucester) made a few remarks, after which

The PRESIDENT called upon Dr. F. W. PAVY, F.R.S. (London), to read his paper on

Experimental Glycosuria.

The main points of Dr. Pavy's paper were as follows. Glycosuria might be taken as meaning the presence of sugar in the urine in quantity sufficient to be recognisable by the ordinarily employed rough methods of testing. Strictly speaking, however, normal urine contained a certain amount of sugar which escaped being revealed by rough testing but which was susceptible of recognition by more delicate methods of procedure. This was not taken into account in connexion with the consideration of glycosuria. Under normal circumstances, although carbohydrate matter might enter largely into the food ingested, no glycosuria was observed. It therefore followed that the system had the power of dealing with it in a manner to obviate its escape in an unutilised state, as sugar, with the urine, and he thought it might be said that physiologists now for the most part concurred with the view that it was placed in a position for utilisation and its escape as sugar thereby was prevented by the assimilative action of protoplasmic matter. Living protoplasm was endowed with the power as a property throughout nature of taking appropriate matter and incorporating it into itself. In this way absorbed alimentary carbohydrate became drawn into the proteid molecules of which protoplasm consisted—for the essential constituent of protoplasm was proteid—and subsequently subjected to the influence of conditions resulting in one way or other in utilisation. Assimilation thus stood as a preparatory step to utilisation, and when the absorbed carbohydrate of food was fully assimilated and afterwards properly turned to account no glycosuria occurred. Experimentally induced glycosuria carried them over a vast extent of ground. The conditions giving rise to it were multitudinous and diverse. Here Dr. Pavy gave a list of conditions leading artificially to the production of glycosuria. With such a chaotic list before them it was difficult to see upon what ground they stood with respect to the manner in which the several conditions acted in producing glycosuria. The best way of meeting the difficulty would be, it appeared to him, to look to the sources from which in connexion with the operations of life the eliminated sugar could be derived. Thus viewed the origin of the sugar of glycosuria could be shaped for consideration under four heads: (1) it might be derived from unassimilated carbohydrate; (2) it might be derived from stored glycogen abnormally passing into sugar which thereafter found its way into the urine; (3) a third source for the sugar of glycosuria was proteid matter (by an abnormal breaking-down process sugar became cleaved off and subsequently eliminated in the urine); and (4) the question of a fourth source from fat would be discussed. They knew that as a normal occurrence in the vegetable kingdom fat was extensively converted into carbohydrate. It was a matter for consideration if under abnormal conditions fat in the animal kingdom could constitute a source of sugar in connexion with glycosuria.

Glycosuria from unassimilated carbohydrate.—Under ordinary circumstances carbohydrate was ingested and nothing was seen of it afterwards. After absorption it was assimilated or put into a condition for passing to utilisation, and the latent energy which it contained was given out in one form or other of force. Failing to follow this course, it remained in the form of sugar and was eliminated as such with the urine instead of being consumed and yielding energy to the system. Taken to an ordinary extent under healthy conditions, observation showed that the urine remained uninfluenced,[1] and the same might practically be said to apply to the systematic blood, so that the blood and urine stood in this respect in parallel positions. By excessive ingestion of carbohydrates, however, a glycosuric state might be induced. Dr. Pavy had recognised this fact at the outset of his experimental research work. Others had obtained confirmatory testimony, and it might be looked upon as an established fact that glycosuria was producible in the healthy state by an excessive ingestion of carbohydrate matter which might be taken as meaning that the assimilative power was not unlimited and that it could be over-stepped. Seeing that glycosuria was susceptible of being produced by sugar introduced into the alimentary canal it might naturally be expected to follow intravenous and subcutaneous injections; and upon this point, without entering into particulars regarding the specific differences for the various sugars, he needed only to say that when administered in this way small quantities sufficed to throw sugar into the urine. It could definitely be said that one important direction in which alimentary carbohydrate passed was into fat. In the fattening of animals, which constituted an extensive industry, they had an illustration of this application. As he had elsewhere pointed out, he believed that this conversion occurred in the villi, which were in continuity with the lacteal system, and in the liver. Both stood in a position to block the passage of sugar into the general circulation. Another important application of carbohydrate was into the construction of proteid. Failing to be transformed into fat or synthesised into proteid the carbohydrate would reach the portal system as sugar and thence would be conveyed to the liver. Here transformation into glycogen occurred. By the cells of the liver the sugar was picked out and its molecules were dehydrated and, as it was termed, condensed or converted from the monosaccharid to the polysaccharid state. This must be regarded as the result ot protoplasmic action, presumably comparable to that which led to the deposition of starch, cellulose, &c., in the vegetable organism, and, like starch, glycogen occupied the position of a convenient storage or reserve material. They learnt then as regards the point under consideration that carbohydrate became disposed of within the system by the assimilative influence of protoplasm, and that whatever was not so disposed of was met with in the general circulation as sugar and thence constituted a source of glycosuria proportionate in degree to the glycæmia existing.

Glycosuria from the abnormal transformation of stored glycogen into sugar.—Dr. Pavy had hitherto been giving attention to glycosuria due to sugar that had not been dealt with by the system. He now passed to glycosuria due to sugar drawn from assimilated carbohydrate. Glycogen was one issue of assimilative action. It consisted of the small molecules of which sugar was composed, condensed, or built together into a large-sized molecule—a kind of synthesis in reality, with an accompanying setting free of a definite amount of water—and was a product derived from the operations of living protoplasm. By enzymic and other means it was readily broken down and hydrolysed into sugar molecules from which it was constructed, and, with the occurrence of this phenomenon the sugar of glycosuria might be produced. The liver and the muscles were the chief seats of glycogen accumulation. Much of a definite nature could not be said about the precise condition in which glycogen existed further than that it was so circumstanced as to form a store, which might be held and utilised as occasion might require He had suggested that the glycogen existed "in feeble combination with nitrogenous matter" The proposition advanced by Nerking was that only the glycogen that was susceptible of extraction with water was in the free state and that the rest was in combination, apparently in a glucoside like body, with proteid In illustration of what was here spoken of—and it supplied them with a representation of the modern views of the chemistry of life—he might refer to what was found to occur in the case of the oxidation of tyrosine in the living body to benzoic acid and the subsequent union of this with glycene to form hippuric acid Tyrosine consisted of a benzene ring with a fatty side chain linked to it By oxidation the elements of the side chain became removed leaving the benzoic acid with the benzene ring intact This afterwards uniting with glycene met with in the body forms hippuric acid and water which became eliminated with the urine Extending this line of action to carbohydrate it was believed that carbohydrate groups existed linked on as side chains to the nitrogenous nucleus and that these side chains might be oxidised off or otherwise detached without [illegible] lycogen, as was well known [illegible] into sugar in the presence of a diastatic enzyme and what took place in the liver immediately after death showed that there was no lack of enzyme existing or producible After death, for instance, sugar was produced in the liver in a manner that, it might be taken, could not possibly be occurring during life and if somatic death was occasioned in such a way as to permit of the circulation being maintained by artificial respiration a glycosuric state followed

---

[1] Breul: Archiv für Experimentelle Pathologie, 40, 1898.

Glycosuria arising from the disruption of proteid with a liberation of sugar—In this form of glycosuria originating from assimilated carbohydrate it might be considered that the carbohydrate was not to a similar extent free to pass into sugar, as in the form that had been dealt with. When the carbohydrate was bound up in, and thus constituted an integral part of, the proteid molecule the molecule must as a preliminary step be broken down and the carbohydrate liberated before it could present itself to their cognisance as sugar As long as it was contained within the molecule it was virtually lost to view and could only become manifest to them again on being set free Thus it happened that a sugar and nitrogen elimination occurred as a result of proteid disintegration and when there was no other source than proteid disintegration for the sugar eliminated the two were found to hold a definite relation the one to the other Pancreatic and phloridzin diabetes were forms of diabetes which were accompanied with proteid disintegration as a source of the eliminated sugar They at the same time also cleared away as urinary sugar the stored glycogen and the carbohydrate linked as side chains to the proteid molecule When all this had been effected in the starved animal the nucleus of the molecule next went and then it was that the definite relation between the eliminated dextrose and nitrogen was observed The first effect then in connexion with pancreatic and phloridzin diabetes was that looking at the dextrose and nitrogen elimination the former stood in high relation to the latter This lasted as long as there was a source for dextrose other than the carbohydrate intimately locked up in the proteid molecule Subsequently in the starved animal the proportion of dextrose fell and ultimately it held a pretty constant relation of a little under 3 to 1 of nitrogen The source of dextrose was now breaking down proteid matter which resulted in the elimination of both the [illegible] parts The ratio of [illegible] hus give an insight [illegible] he original proteid, and as proteid contained about 16 per cent of nitrogen calculation based upon a 3 to 1 ratio of elimination gave about 50 per cent. as the amount of carbohydrate contained in the proteid molecule Some had worked out the amount as standing a little higher, but whatever the precise amount it was seen that proteid constituted an important source of sugar in connexion with glycosuria. The glycosuria and concomitant conditions attending removal of the pancreas stood in accord in all particulars with diabetes as it occurred in the human subject. Glycæmia was an antecedent of the glycosuria, and if the escape of sugar was prevented—as by extirpation of the kidneys or by ligaturing the ureters—the sugar might rise to a very large amount in the blood. Phloridzin glycosuria stood in a strikingly different position Phloridzin similarly led to the elimination of sugar by attacking glycogen and proteid but the results of experimental observation were not reconcilable with the glycosuria being preceded by glycæmia. The kidney seemed to be in some way or other concerned in the production of the sugar, and although the close attention of numerous investigators had been given to the subject it could not yet be said that the bottom of it had been reached

The question of glycosuria through the medium of fat—They knew that fat was producible by both the vegetable and animal organisms from carbohydrate and that the production took place upon a large scale in both kingdoms of nature. They knew also that, as was shown in the growth of the oily seeds fat constituted a source of carbohydrate in the vegetable kingdom Analogy was therefore suggestive that in the animal organism the possibility existed that sugar might be producible from fat The point had been mooted and discussed but it must be said that nothing in the shape of tangible evidence had been yet adduced to connect glycosuria with fat as a source Certainly in the diabetic subject, instead of fat consumed as food producing an increase of sugar elimination it seemed to act beneficially by supplying oxidisable material that might save body stuff from destruction At the beginning he had given a lengthy list of conditions productive of glycosuria. Looked at individually nothing in common was discernible to account for their action Indeed they constituted a most incongruous group and left them in a mystified state with regard to them Viewed, however, by the light of the line of consideration that had been adopted there was nothing inconsistent with very varied conditions giving rise to a similar result The position of matters might be expressed in a few words Wrong metabolism was regarded as the source of glycosuria. Under the right course of events the carbohydrate matter of food was assimilated by protoplasmic action and thus placed in the required position for contributing to utilisation That which was not assimilated and remained in the free state passed as sugar through the system and escaped as waste material with the urine. That which had been been assimilated might as the result of wrong metabolism again pass into sugar and constitute a source of glycosuria They had wrong chemistry to deal with and very diverse conditions might give rise to the wrong result that occurred

Professor W H THOMSON (Belfast) said that most forms of glycosuria might be referred to one of four causes 1 Primary excess of sugar in the blood, of which form that resulting from enemata of glucose was especially remarkable, the path of absorption being through the hæmorrhoidal veins and so escaping the liver 2. Diminished metabolism in tissues 3 *Damaged glycogenic function of the liver, of* which form that resulting from the removal of the pancreas was most important This might be explained as follows (*a*) some substance was removed with the pancreas which was necessary to the glycogenic function of this organ—this was not contained in the pancreatic juice, or (*b*) the result of the loss of the pancreatic juice was that a poisonous substance was produced in the alimentary tract which on reaching the liver produced disturbance of its *function* but which *normally* would be neutralised by some constituent of the internal secretion of the pancreas He had proved that feeding with sufficient quantities of argonin a basic product forming part of the anti peptone part of the end product of pancreatic proteolysis would produce glycosuria. 4 Renal glycosuria such as that produced by phloridzin and phloretin in which there was no hyperglycæmia not even when the kidneys were extirpated or the ureters tied showed probably an action on both the liver and the kidney

Professor VAUGHAN HARLEY'S (London) contribution to the discussion was read by the secretary of the section. Glycosuria was, he said, due to one of three causes. 1 Over production of sugar in the organism such as the hyperglycæmia produced by puncture of the medulla oblongata and the various forms of alimentary hyperglycæmia of which latter an illustrative case was given showing that the correct treatment of this form consisted in proper diet containing a suitable quantity of carbohydrate material 2. Mal-assimilation of sugar by the tissues—e g the hyperglycæmia produced by removal of the pancreas in dogs 3. Anomalous forms—e g, that produced by the administration of phloridzin which was due to increased permeability of the kidney

Sir W H BROADBENT (London) said that the mere presence of sugar in the urine was of secondary importance in glycosuria, the mal-assimilation by the tissues was a much larger point. If the liver were the chief organ at fault, why was there not glycosuria in every case of advanced cirrhosis of that organ?

Professor R. J. ANDERSON made some remarks.

Dr. PAVY then replied, agreeing with Sir W. H. Broadbent that the liver had little to do with many cases of glycosuria; thus it might be entirely cut off from the circulation, after which the administration of phloridzin still produced glycosuria. The early stages of many cases of diabetes were no doubt due to mal-assimilation of carbohydrate material; in these the later stages always went beyond this and were essentially due to a breaking-down process of the tissues themselves.

Mr. N. BISHOP HARMAN (London) read a paper on

Socia Thymi Cervicalis and Thymus Accessorius.

The former condition, he said, was found in a full-timed fœtus; a left lateral prolongation of the thymus extended into the neck to the angle of the jaw. It was fleshy and showed the histology usual to the thymus. It had a special blood-supply. The occurrence was identical with the normal symmetrical prolongation in birds and lambs and probably showed the retention of an original connexion of the gland mass with its site of origin. The vagus encircled part of the socia which might represent the relation of the lateral branches of the vagus to the thymic dorsal extension of the gill-pouch. The latter condition was of a case similar to that described by Henle. Its significance was discussed. Embryologists placed the origin of the human thymus from gill-pouch III De Meuron showed that in the passage from lower to higher animals the extent of the origin was diminished—e g, rays used five pouches, sharks four, and sheep two, three, and four, and in the sheep the derivative of the fourth was a small portion similar to this accessory thymus. This condition in man might indicate a possible origin from the third and fourth pouches.

Mr. HARMAN also showed a young Hottentot skull obtained from Bulawayo. The facial and orbital regions showed conditions which appeared to be either a very rare condition of the processus nasalus, owing to a marked sutura notha or else the presence of enormous facial lacrymal bones. Besides there were an absence of orbital lacrymals and the presence of prefrontal ossicles. The internasal suture was closed and the capacity and other features of the skull were of a low type. Age under 21 years.

The PRESIDENT said that the condition was of great interest; he thought that it was due to an accentuation of the sutura notha.

PATHOLOGY AND BACTERIOLOGY.

WEDNESDAY, JULY 31ST.

Presidential Address.

Dr. J. W. WASHBOURN (London) delivered his presidential address on

Some of the Principal Diseases Met with among the Troops in South Africa during the Present War.

The Imperial Yeomanry Hospital at Pretoria, of which Dr. Washbourn was in medical charge, was opened in August, 1900, and between then and the end of April, 1901, 3702 cases in all were treated in it. Of these 2853 were medical and 849 were surgical. The medical cases included 546 cases of enteric fever, 379 of dysentery, 340 of debility, 296 of rheumatism, 258 of malaria, 187 of simple continued fever, 152 of diarrhœa, 93 of jaundice, 71 of influenza, 70 of tonsillitis, 43 of bronchitis, two of acute rheumatic fever, whilst the remaining 405 cases included various diseases, none of which were numerically important. If the cases of jaundice, enteric fever, dysentery, and diarrhœa were added together it would be seen that they included 1170 cases out of the total of 2853 treated. Dr. Washbourn's surgical colleagues in the hospital had told him that amongst their cases diseases of the rectum, especially hæmorrhoids, occupied a very prominent position. On the other hand, diseases of the lungs were exceptionally rare, only 43 cases of bronchitis and an occasional case of pneumonia were admitted. From these facts it might be concluded that in South Africa the food was bad and the air was good. The diseases of the rectum were, he thought, no doubt due to improper food—the absence of vegetables, for example—whilst the other intestinal diseases were due to contamination of food with specific germs. Under proper sanitary conditions enteric fever, dysentery, and probably diarrhœa, would diminish enormously; and had there been a proper sanitary corps, under the supervision of a good sanitary medical officer, to look after the standing camps, he believed that a large proportion of the cases of these diseases would have been avoided. Great difficulties in the way of sanitary measures certainly existed when the troops were on trek, but they did not exist when troops were in a standing camp; everyone with experience in campaigning knew that sickness did not develop among troops on the march but arose soon after they were stationed in a standing camp. And it was under the latter condition that sanitary measures could be, and ought to be, enforced. Next in numerical importance to intestinal diseases came cases of debility; these did not require any special treatment, they were simply cases of men requiring a few days' rest which they could not obtain whilst with their regiment. Next in numerical importance came cases of chronic muscular rheumatism, of which 296 were treated. Only two cases of definite rheumatic fever were admitted, and both patients had had the disease before in England. Altogether Dr. Washbourn had only seen a few cases of rheumatic fever in South Africa, and in every single case the patient had suffered from the disease before he landed. The rarity of acute rheumatic fever and the frequent occurrence of chronic rheumatism showed that the two diseases had no etiological connexion. He could not help thinking that this muscular rheumatism was more nearly related to gout than to rheumatic fever, and he was inclined to attribute it to the nature of the men's food and especially to the absence of fresh vegetables. Then there were a large number of cases of malaria, some, perhaps, incorrectly diagnosed, for many of them went into hospital after the fever had subsided and without characteristic symptoms to guide. In a number of cases the malarial parasite was found; but in other cases of undoubted malaria repeated examination failed to discover it. In all these latter cases quinine had already been administered and this was no doubt the cause of the failure. Malaria was by no means common all over South Africa, but was limited to well-defined areas. It was common in the district north of Pretoria, beginning in the Megaliesberg valley and extending all through the bush veldt. It was also common in the low country east of Waterval Boven; it did not occur in the Karroo or in the Orange River Colony. There were in all 93 cases of jaundice, 71 out of these cases being admitted in January, February, and March. The disease ran a definite course. There was nausea, which might be accompanied by vomiting, or pain to the right side of the epigastrium; the bowels might be regular, loose, or constipated; the temperature might remain normal or there might be moderate pyrexia. In three or four days the jaundice would appear and the stools became clay-coloured. As the jaundice, which was usually intense, appeared the other symptoms usually subsided. After the jaundice had lasted a few days it disappeared and the patient recovered. The symptoms suggested an inflammation of the duodenum, leading to blocking of the bile duct. The jaundice was, therefore, a more or less accidental sequela and not the cause of the symptoms. Dr. Washbourn had, in fact, seen a number of cases with all the initial symptoms but without the subsequent jaundice. The occurrence of the disease in epidemic form pointed to some infective agency, but none had yet been actually discovered. In spite of the intense heat in South Africa Dr. Washbourn had never seen a well-marked case of heat-stroke, and various inquiries amongst the medical officers, who had been on trek with the columns failed to elicit the record of a single case. This showed that something more than the actual heat of the sun was required for the production of heat-stroke, and supported the view that the disease was due to some infection. There were 152 cases of diarrhœa admitted, but the figures gave a very feeble idea of the prevalence of the disease, as they included only such cases as were severe enough to necessitate admission into hospital. Almost everybody after arriving in South Africa was attacked with gastro-enteritis of a more or less severe type. The temperature might be raised for a short period, but usually there was no fever. The motions were liquid and very occasionally contained a small quantity of blood and slime. The symptoms passed off in a day or two as a rule, but the diarrhœa might persist for some weeks without otherwise affecting the health of the patient. The disease appeared to be allied to the summer diarrhœa which occurred in England, and from the incidence of the disease when dysentery was absent Dr Washbourn felt sure that the two diseases had no etiological relationship Of true dysentery 379 cases were admitted and there were nine deaths a mortality of 1 86 per cent The cases might be divided into two types In the first type there were the passage of blood and slime and a fever lasting about six days On the subsidence of the fever the motions gradually assumed their natural character and the patient recovered This was the usual course of the disease, death might however, ensue during the febrile stage or a few days after the fever had subsided In the second type the temperature did not fall at the end of six days but it continued for two or three weeks longer During the latter period blood and slime disappeared from the motions which became liquid, and the symptoms were much more like those of enteric fever than those of dysentery The post-mortem features of South African dysentery were then described. Dr Washbourn had little doubt but that the South African dysentery was the same disease as the asylum dysentery described by Dr F W Mott and Dr Durham in this country He felt sure that it was not due to amœbæ, for he had invariably failed to find them in the motions Abscess of the liver was a rare complication of South African dysentery In one case which occurred both streptococci and a bacillus belonging to the coli group were found, there were no amœbæ in the pus There were 546 cases of enteric fever with 50 deaths a mortality of 9 1 per cent The main features of the type of the disease which he met with were that constipation was much more common than diarrhœa and that phlebitis was exceptionally common In cases which Dr Washbourn had observed during the incubation period he had frequently noticed a preliminary febrile attack which subsided a day or two before the onset of the enteric fever and he thought that this was some indication of the changes which they knew must be taking place during incubation He did not think that inoculation in any way modified the course of an attack and he doubted whether it had any important practical influence upon the incidence of the disease The cases of simple continued fever a limited were simply cases in which there was some malaise with a moderate pyrexia possibly some of them were abortive attacks of some specific disease and some of them might be slight attacks of influenza of which latter 71 definite cases were diagnosed Finally Dr Washbourn emphasised the influence of 'a chill as determining the occurrence of an attack of diarrhœa It was an undoubted predisposing cause A chill which in England would probably give rise to an attack of nasal catarrh in South Africa would cause an intestinal catarrh, the difference was probably due to the prevalence of the bacteria causing the respective conditions

Professor T CLIFFORD ALLBUTT (Cambridge) said that he responded with great pleasure to the opportunity given him of appreciating the introductory address of their President He particularly wished to refer to what Dr Washbourn had said as to the preliminary rise of temperature before the onset of enteric fever He himself had many times noticed the occurrence but he had never published his observations as he had kept no definite record of cases As however Dr Washbourn had called their attention to the point he himself was encouraged to give his own experience which was quite in accord with what Dr Washbourn had told them on the point

Lymphadenoma

Professor J MICHELL CLARKE (Bristol) then opened a discussion on Lymphadenoma The term was defined as including those diseases which were characterised by over growth of lymphoid tissue or which gave rise to growths closely resembling in structure the lymphatic glands The points of resemblance between lymphadenoma and an infective process were insisted on and its possible relationship to tuberculosis to the sarcomata, and to lymphatic leukæmia was discussed. Professor Michell Clarke concluded with a reference to the condition described as status lymphaticus, or lymphatism in which there was a partial or general hyperplasia of lymphatic glands, especially the pharyngeal thoracic and abdominal enlargement of the spleen and tonsils also occurred. There was frequently a remarkable hyperplasia of the intestinal lymphatics, 'individual glands standing out like peas to borrow Osler's description. The cause of death in such cases was now attributed by Paltauf and others to deficient powers of resistance and not, as formerly, to coincident enlargement of the thymus.

In the discussion which followed Mr H J STILES (Edinburgh) Dr J H BRYANT (London) the PRESIDENT, and others took part and a communication on the subject rom Dr LOVELL GULLAND (Edinburgh) was read by Dr W S LAZARUS BARLOW (London) The speakers were generally in accord with the views which Professor Michell Clarke had laid down and the possible relationship between tuberculosis and some cases of lymphadenoma was emphasised by several

Dr J W H EYRE (London) read a communication on a Form of Centrifuge which he had devised for dealing with large quantities of milk for bacteriological examination, using hand power a speed of 2500 revolutions per minute was readily attained and with electric power a greater speed could be reached.—The paper was discussed by the PRESIDENT Dr LAZARUS-BARLOW Dr J O SYMES (Bristol) and Mr A G R FOULERTON (London)

The next paper read was by Dr SYMES on the Bacteriological Examination of the Blood Dr Symes pointed out the advantages of the method now in general use of drawing the blood for examination directly from a vein A considerable percentage of Dr Symes's examinations in infective diseases had given positive results cultures of streptococci staphylococcus albus and other organisms having been obtained from cases of puerperal septicæmia ulcerative endocarditis and in other conditions—This paper was followed by a very thorough discussion in which the PRESIDENT, Dr A C F RABAGLIATI (Bradford) Dr F G TREVITHICK (Cheltenham) Dr DALAND (Philadelphia) Dr EYRE and Dr O I GRUNBAUM (London) considered the technique employed and contributed altogether a considerable number of cases in which positive cultures had been obtained from the blood during life

Dr J J DOUGLAS (London) read a paper on the Arrangement of Nissl's Bodies in Nerve Cells It was pointed out that the arrangement of the chromatophile granules as shown by Nissl's method varied in cells from different parts of the central nervous system In the cells of the anterior cornua the chromatophile granules were aggregated in very definite masses which were distributed in a more or less uniform manner throughout the cell protoplasm In the cells of Clarke's column on the other hand the Nissl bodies had a more or less distinctly peripheral distribution large aggregations of the bodies being found at the periphery whilst the perinuclear area was comparatively free from them Some excellent microphotographs in support of this were shown which clearly demonstrated the points raised in the paper

OPHTHALMOLOGY

WEDNESDAY, JULY 31ST

Presidential Address

Mr W H JESSOP (London) opened the first meeting of the section with an address in which he alluded to his boyhood in Cheltenham and the establishment of the local eye hospital by his father who was a school-fellow of Mr Henry Power He then proceeded to speak of the pathology of glioma basing his remarks on six cases which had come under his notice in the past two years Five specimens were exhibited in different stages and in two cases both eyes were involved. Mr Jessop gave a minute description of the cases and specimens the growth being regarded by German pathologists as neuro-epithelioma (Wintersteiner) They assumed at different periods three distinct stages (1) early, exhibiting microscopically the rosette appearance characteristic of the growth and only slight degeneration, (2) middle glaucomatous—vascular development with columnar cells some 30 deep along the vessels and degeneration beyond and (3) late—shrinkage of vessels almost complete degeneration of the new growth and rapid extension along the optic nerve After this the growth became extra ocular assumed the character of a round-celled sarcoma with marked malignancy showing itself by recurrence and metastasis In the intra-ocular condition the malignancy was limited The two cases in which the eye was removed in the early stage remained well after two years and the patient would be practically safe after one year

Mr PRIESTLEY SMITH (Birmingham) opened the discussion on

Myoma

which might be either stationary or progressive with damage to the tissues of the eye and diminution of vision The important question was How were they to distinguish a simple from a pernicious myopia? The speaker exhibited a reduced chart representing the degree and progress of 100 cases, which showed that there was no actual dividing line between the two varieties, but that the chief progress took place during adolescence. The chief data in regard to prognosis were:—1. Age.—The younger the patient the more likely the disease was to be progressive. The tendency was most marked during the period of growth 15 to 25 years, after which it ceased. 2. Degree.—The higher the myopia the more likely it was to increase, especially in young subjects. In adults no forecast could be made. 3. Condition of choroid and retina—These changes were more marked in the pernicious cases They included myopic crescent, thinning of the choroid, pigmentation of the retina, and displacement of the disc. Diffuse changes from stretching and vascular disturbance occurred later. Syphilis caused sclero-choroiditis. Congestion and inflammation were important factors. 4. Constitution.—Malnutrition and lactation tended to make the disease progressive, as also did chronic constitutional disease and high arterial tension. 5. Heredity.—Inherited myopia was often simple, but there was no immunity from progressive myopia. 6. Occupation.—Any form of close work was harmful. As to treatment, all cases of myopia should be suspected, especially in the young, of being progressive till time proved the contrary and should be treated accordingly. There should be re-examination in six months and one year. Prevention of progressive myopia was more helpful than attempts at curing.

Mr. A. S. **PERCIVAL** (Newcastle-on-Tyne) thought the contractions of extra-ocular muscles important factors in squeezing the eye and causing elongation. He recommended reading in such a position as obviated inclination of the eyes, especially downwards, and thought he could trace arrest of progressive myopia to this means in four cases.

Mr. **HENRY POWER** (London) recommended work or reading only in a good light—not at all at night. The head should be in the upright position. There should be no stooping. Good diet should be given in childhood, especially when at school. No work should be done before food.

Dr. **DARIER** mentioned traumatic astigmatism or myopia of from four to eight dioptrics from a blow on the cornea causing overstretching of the suspensory ligament of the lens. Contrarily, pressure on the eye appears to help vision in hypermetropia and presbyopia. Massage of the globe improved the circulation and tension of the eye and so increased vision. Gentle pressure on the cornea through the lids should be applied daily for from two to three weeks.

Dr. A. H. **THOMPSON** (London) thought that a well-defined crescent, single, double, or treble, with choroiditis at the edge and aching in the eye were unfavourable signs.

Mr. H. **EALES** (Birmingham) said that power of accommodation varied much with glasses in myopia; some high grades had wide range, while others of low degree had a very narrow one. He recommended full correction and avoidance of close work. Painful convergence for near objects could be remedied by prisms and more particularly by proper centreing of glasses. Spectacle frames were usually made two and a half inches wide, whereas some patients had as much as three inches between the centres of their pupils.

Dr. J. **BOWER** (Cheltenham) said that bad light and too close position of a book or work most needed correction. He deprecated gymnastics which involved hanging the head, as trapeze exercise. Patients with low myopia (three dioptrics) could dispense with glasses for distance, but those with higher grades should wear them continuously.

Dr. E. E. **MADDOX** (Bournemouth) considered that it was more necessary to avoid fatigue of the eyes than accommodation or convergence. The higher the myopia the greater the strain on the tunics owing to the larger surface exposed to expansive pressure. Any tendency to look through the edge of the glasses called for full correction. He recommended gentle massage of the sclero-corneal junction as having a good effect on tension by aiding the transfusion of fluid. Convergence rarely occurred without looking down, due to the action of the inferior rectus, which should be avoided.

Dr. A. **BRONNER** (Bradford) asked whether myopia when progressive could be arrested by glasses. Hæmorrhages in women usually resulted from vascular change during menstruation. In men syphilis was the cause.

Dr. R. D. **BATTEN** (London) thought that all cases were more or less progressive; he attached much importance to tilting of the disc and distortion of the vessels, with thinning of the anterior part of the sclerotic and occurrence of astigmatism.

Mr. **TATHAM THOMPSON** (Cardiff) said that myopia was not often recognised in infancy. The habit of holding a book close should be broken, whether before or after correction by glasses.

Mr. **PRIESTLEY SMITH**, in reply, said no distinct line existed between innocent and pernicious myopia. He had given his views on treatment fully in the *Ophthalmic Review* for 1890. Muscæ volitantes were only of importance when apparent to the observer. Most people could see them themselves. He thought that the observation made by Dr. Darier was very interesting and important, but pressure could not be applied safely in all cases.

Major H. **HERBERT**, I.M.S. communicated a paper on

Superficial Punctate Keratitis,

describing a vesicular corneal eruption on the cornea, occurring during the rainy season in Bombay, associated with micro-organisms and lasting from two to three weeks in young adults.—Mr. **DEVEREUX MARSHALL** (London), Major **DRAKE BROCKMAN**, Mr. C. **BLAIR** (London), and the **PRESIDENT** spoke.—It was recommended that the term "keratitis punctata" at present used for the effects of cyclitis on Descemet's membrane should be abolished.

Mr. **TATHAM THOMPSON** described as unique a case of Symmetrical Bullous Eruption around the Cornea in Both Eyes with Acute Photophobia and Congestion lasting three weeks and cured by formol, 1 in 5000, after application of atropine and cocaine.—The **PRESIDENT** mentioned other cases of greater severity and duration.

Mr. C. **BLAIR** described an Unusual Form of Keratitis associated with Papular and Pustular Skin Eruption. The attacks lasted a few days twice a year.—Mr. D. **MARSHALL** suggested tuberculosis.

Mr. **PERCIVAL** described the Application of Periscopic Glasses to Give Lateral Vision without Rotating the Head.—The **PRESIDENT**, Dr. **MADDOX**, and Mr. **TATHAM THOMPSON** expressed their appreciation of the method. The expense of the glasses was increased from 50 to 100 per cent.

DISEASES OF CHILDREN.

WEDNESDAY, JULY 31ST.

The **PRESIDENT**, Mr. **FREDERIC EVE** (London), after a few introductory remarks, called upon

Mr. **BERNARD PITTS** (London) to open a discussion upon the subject of

The Treatment of Intussusception.

In the course of his paper Mr. Pitts laid before the section a complete list of all the cases of intussusception in St. Thomas's Hospital (on the surgical side) from 1875 to 1900 inclusive. He pointed out that distension of the bowel might be tried, if the case was very recent, under an anæsthetic and holding oneself in readiness to do an abdominal section, if necessary, at once. A severe case should at once be explored, without any previous inflation, as this only added to the shock. The intussusception should be brought outside the wound, as then the condition could be examined. If reduction were impossible resection of the bowel should be done. If gangrene were present the case was almost hopeless, as prolonged operations were not well borne by children. The sooner the child was placed in the hospital after the symptoms appeared the better. At the first onset it seemed reasonable to inflate the large bowel, but it was never certain that inflation completely reduced the swelling, and the uncertainty as to the exact condition of the bowel made it better for the surgeon to see and to handle it. The swelling of the mesenteric glands which occurred in children in intussusception, hindered reduction. Inflation might be used as a preliminary to operation. The risk of shock must be minimised by all possible means in a young child. It was better not to let the small bowel escape out of the incision, so if there were very much distension he would make a small opening into it and let out the contents—i.e., gas—and then sew it up. A great danger of reduction was the chance of splitting the coat of the bowel. If reduction were very difficult he would open the sheath and reduce by a finger inside the bowel. If this were impossible he would resect the bowel *in situ*. He then referred to a diagram of a case of ileo-colic intussusception where the portion inside the colon was removed, and to another where there was invagination of the appendix. In a third case the small bowel was implanted into the large one above the old ileo cæcal valve In a gangrenous case 24 inches of [illegible] service [illegible] thorough [illegible] as to have no prolapse of the intestines According to the list of cases chronic intussusception was quite rare in children In fatal cases the temperature frequently ran up at once after operation to a great height from no very certain cause In cases brought to hospital it was better to operate at once and to try inflation also so as to get the bowel back to near where the incision should be made In gangrenous cases the ends of the bowel should be brought outside the body and continuity should be established later If very extensive resection and restored continuity with Paul s buttons should be done at once

The **PRESIDENT** then pointed out the various subjects for discussion.

Mr **D ARCY POWER** (London) presented a table of cases occurring at St Bartholomew s Hospital and the Victoria Hospital for Children Chelsea during the years 1891–1900 Of 65 cases the total recoveries were 23 and the total deaths were 42 Thirty cases presented points of especial interest as follows two patients recovered spontaneously one acute and one chronic case, one recovered from a triple intussusception, one died from ileus after reduction, one had intestinal obstruction due to adhesions after the abdominal section, two were too ill to operate upon; one had such extensive adhesions that nothing could be done, three cases recurred repeatedly after apparent reduction by irrigation, in three cases the intussusception was overlooked at the operation and was found post mortem, in one case there was no intussusception, 15 cases needed excision of the bowel, in seven cases an artificial anus was made—all fatal, in five cases Murphy's button was used—four patients died and one recovered, in two cases Maunsell s operation was performed—both patients died, and in one case a circular enterorrhaphy was done—the patient died Mr Power was a whole hearted advocate of the earliest possible abdominal section and he gave details of cases which had brought him to this opinion Irrigation or inflation might be tried before the operating surgeon could arrive and was also useful to reduce the size of the tumour before operating

Mr **MCADAM ECCLES** (London) advocated early diagnosis and immediate laparotomy if circumstances permitted it, the earlier the operation the less danger of septic absorption—this might explain the high temperature in fatal cases There were three kinds of temperature after these operations (1) normal which went on all right, (2) low, where shock was the cause, and (3) high, where there was probably absorption of toxic products from the surface of the intussuscepted bowel, so he always washed the bowel carefully with biniodide of mercury Irrigation or inflation should always be under an anæsthetic It was very hard to say whether reduction was successful Everything should be ready for an operation so as to lose no time The sutures should be close and numerous through the whole thickness of the abdominal wall and be left in for a fortnight The occurrence of intussusception was probably due to bad feeding so the suturing was most important In one case irrigation done after the tumour was outside the body was a great help in reduction The child should not take the breast for 24 hours after operation, but the mother s milk should be drawn off and given in a spoon To avoid shock an injection of two ounces of milk at 105° F into the rectum after operation should be made Small doses of opium were most useful to ensure quietude after operation The recurrence years afterwards might be due to a thickening of the bowel wall.

Mr **A H TUBBY** (London) strongly supported an abdominal operation forthwith as did

Mr **F C ABBOTT** (London) who suggested that the septic absorption took place from the inner surface of the affected bowel He quoted a case of tuberculous peritonitis closely simulating intussusception He used two layers of sutures and injected a saline solution at the end of operations to prevent shock

Mr **J P BUSH** (Clifton) also advocated early operation, as the intestine of children would only stand a very little water pressure The less washing out the better, and he preferred the operation as suggested in two stages

Dr **SINCLAIR WHITE** (Sheffield) described three cases which exhibited hyperpyrexia and dealt with the question of inflation *versus* operation for practitioners not used to such operations He preferred to protect the small bowel if it protruded rather than to open it

Dr **LEWIS MARSHALL** (Nottingham) pressed for early operation for close and thorough suturing, and for the use of strychnine to prevent shock.

Mr **C F CUTHBERT** (Gloucester) was glad that there was no uncertainty as to the need for early operation in these cases

Dr **MANSEL SYMPSON** (Lincoln) urged the advisability of early operation and gave details of a case where distension of the bowel was successful after replacing the portion extruded at the anus He also dealt with the question of hyperpyrexia and the difficulty of closing an artificial anus

Dr **A G FORSTER** (Cheltenham) advised opening the gut to relieve distension

Professor **MCPHEDRAN** (Toronto) advocated early operation

Dr **BLACKADER** (Montreal) advocated the same

Dr **F E BATTEN** (London) commented on the increase of cases of this complaint one reason given being that they were diagnosed earlier Another factor was the bad feeding of the children of the lower classes and the frequent dosing with powerful purgatives It was said to be a rare disease in France

The **PRESIDENT** considered that inflation or distension of the bowel was inefficacious in the great majority of cases and the return of symptoms was due to illusory reduction Inflation and distension formed a haphazard proceeding because the intussusception so often commenced in the small intestine and in children so frequently the ileo-cæcal valve was competent He called attention to a form of this disease where the intussusception began in the caput cæci and where after reduction a part was left projecting convexly into the colon This had had to be sutured so as to make it concave internally He mentioned a case of Meckel s diverticulum and a tuberculous ulcer causing the intussusception He had come across appendicitis simulating this complaint.

Mr **PITTS** briefly replied

LARYNGOLOGY AND OTOLOGY

WEDNESDAY, JULY 31ST

This section met under the presidency of Mr **T MARK HOVELL** (London) The President did not give an address but proceeded immediately with the work of the section which included two discussions and a plethora of papers

Mr **F MARSH** (Birmingham) Dr **A. BROWN KELLY** (Glasgow) and Mr **C A. PARKER** (London), opened a discussion on

The Treatment of Nasal Obstruction from Intra nasal Causes other than Mucous Polypus

Mr **MARSH** defined nasal obstruction as inability to breathe freely and equably at the same time through both nostrils He proceeded to describe some of the more common forms of intra nasal obstruction and the methods usually adopted for dealing with them

Dr **KELLY** continued the discussion with a paper in which he dealt more particularly with the method of treating enlargement of the turbinated bodies. The introduction of the finger into the naso-pharynx to adjust the snare for the removal of the enlarged posterior end of the inferior turbinated body he considered was unnecessary and he advocated the performance of this operation under the guidance of anterior or posterior rhinoscopy Excessive hæmorrhage resulting from the operation he considered need not be feared it had not occurred in his experience In dealing with these posterior hypertrophies it was well to keep the following facts in view (1) that no amount of treatment applied to the anterior two-thirds of the turbinate would appreciably lessen the size of the posterior third, (2) that removal of a hypertrophied posterior end was not infrequently followed by subsidence of the swelling of the rest of the turbinate—the snaring of the posterior end should therefore be undertaken at an early stage in the treatment of these cases (3) that after removal of what at the operation appeared to be the entire posterior end considerable enlargement might still be present when healing had taken place—this was probably due to swelling of the parts immediately anterior to the line of section, and (4) that after removing the posterior end on one side that on the other, which previously appeared normal might become enlarged

Mr **PARKER** dealt chiefly with the indications for operation and based his remarks on the results of [illegible] investigations carried out for determining the direction of the air-currents in the nose which proved that the air traversed the middle and superior passages in inspiration and the lower meatus in expiration. The method employed for determining the inspiratory air-way was puffing lycopodium into the air the patient was breathing and afterwards noting its distribution within the nose. It was thought that the same method might be used with advantage for determining what structures were causing obstruction and how much of such structures required removal in order to restore free nasal breathing. It was important thus to limit operations, for probably the mucous membrane lining the middle and superior passages assisted in warming and moistening the inspired air. As inspired and expired air followed different courses in passing through the nose it was advisable to differentiate between inspiratory and expiratory difficulties; the questions of the drainage of the cavities and the possibilities of abnormalities causing chronic rhinitis should also be considered when dealing with nasal obstruction. As regards inspiration it seemed that alterations in the inferior meatus (with the exception of dislocations of the anterior end of the septal cartilage) caused no trouble because the air passed above them into the middle meatus; even slight alterations in the middle meatus, on the other hand, caused obstruction and required treatment. Enlargements of the middle turbinate also assumed considerable importance as they prevented the passage of air from the middle to the superior meatus. Such enlargements were found in connexion with rhinitis sicca, muco-purulent rhinitis, and commencing or established polypi, under all of which circumstances removal of the anterior end of the middle turbinate was indicated. The method employed for determining the course of the expiratory air-stream was the exhalation of tobacco-smoke. From the results obtained thereby and from the patient's subjective sensations it was evident that it required far greater abnormalities to render expiration difficult than it did to impede inspiration. Though normally the expired air passed through the inferior meatus it seemed easily diverted in cases of obstruction into the middle passage without causing difficulty, whereas even slight obstruction to the inspiratory air stream caused considerable difficulty. Operations on abnormalities of the inferior meatus were, therefore, seldom indicated for the relief of expiratory obstruction unless the middle meatus was at the same time more or less obstructed. The condition which most often caused stenosis of the inferior, and partial obstruction of the middle meatus was enlargement of the posterior end of the inferior turbinate. In such cases expiration was often more difficult than inspiration and operation was indicated. Efficiency of the drainage of the nose was thought to be important to the health of the cavities. The secretions gravitated to the inferior meatus, from which they were easily expelled on blowing the nose. If obstruction existed in the lower passage the expiratory air-stream was, as had already been said, diverted into the middle meatus, naturally losing much of its force, and hence the secretions tended to collect and to cause irritation. If the obstruction in the lower meatus was very great some of the secretions might remain in the middle meatus and set up inflammation there. Consequently operation was indicated in those cases in which secretions were found collecting within the nasal cavities or where great difficulty was experienced in expelling them. As regards the possibility of spurs and deviations, causing chronic rhinitis and its sequelæ by their mere presence, this was thought to be very rarely, if ever, the case. Unless such deformities caused either respiratory difficulties or inefficiency of drainage they might be looked upon as quite innocent of all harm. There was, however, one exception to this statement—namely, in cases of hay fever and asthma, where a spur, for example, might add to the temporary obstruction and increase the irritation. Under these circumstances it was sometimes advisable to remove spurs, and very occasionally even complete turbinectomy might be indicated.

Mr. Mayo Collier (London) pointed out the importance of adding the words "at all times" to the definition that had been given of nasal obstruction; he referred to cases in which the obstruction was experienced only at night upon lying down and spoke of them as cases of "latent obstruction."

Dr. Herbert Tilley (London) recommended subcutaneous section of the anterior end of the inferior turbinate body in cases of extensive hypertrophy of the mucous membrane, a method introduced by Delavan. Puncture and insertion of the galvano-cautery point secured the same end—i.e., the production of an internal cicatrising process which braced up the mucous membrane without destroying its physiological function. The posterior end was best removed by the cold wire snare, the index finger being passed into the naso-pharynx to guide the loop over the swelling. There was little pain in this if the naso-pharynx was slightly cocained and still less if the patient was assured that the discomfort would be only momentary. He disliked the use of the galvano-cautery snare in such close proximity to the Eustachian orifice; he concurred in the view generally expressed that complete turbinectomy must be very rarely required.

Dr. J. Donelan (London) had found considerable advantage from the use of a five-grain tabloid of suprarenal substance at bedtime in the cases which had been described as of temporary nocturnal occurrence, and in which an operation could hardly be recommended. The patients experienced great comfort and in some cases complete relief for about 12 hours after the administration.

Dr. L. H. Pegler (London), Dr. W. Milligan (Manchester), Dr. StClair Thomson (London), and Dr. Scanes Spicer, amongst others, took part in the discussion.

The President congratulated the section upon the decided advance that had been made in the views entertained about the treatment of some of the forms of nasal obstruction which they had had under discussion. He was very pleased to hear such decided expressions of opinion against the reckless removal of the inferior turbinate body. For the removal of the posterior end of this body, when hypertrophied, he preferred the cold wire as being safer in such close proximity to the Eustachian tube. He entertained no fear of hæmorrhage in such cases; he referred to the cases in which, after the removal of adenoids, the obstruction of the nose remained which was due to the enlargement of the posterior ends of the inferior turbinate bodies, and advised the removal of the posterior end more frequently than was usually done in such cases. Septal spurs, in his experience, could be conveniently removed with the scalpel.

Mr. J. Mackie (Nottingham) read a paper upon Practical Points in the Treatment of Nasal Suppuration, especially of the Accessory Sinuses. The paper was illustrated by a long series of cases which had been carefully tabulated and included several of sphenoidal sinus suppuration.

TROPICAL DISEASES.

Wednesday, July 31st.

Stone in the Tropics.

After the address of the President (Major Ronald Ross, I.M.S.), which was published in The Lancet of August 3rd (p. 339), a discussion on the above subject was opened by Mr. P. J. Freyer (London). He introduced the subject by a consideration of the distribution of urinary calculi in India, hoping in this way to help in elucidating the cause of the complaint. The question of phosphatic calculi would not enter into the discussion because the cause of these was well known to be due to the effect of changes in the bladder and urinary tract generally; consequently only the oxalate of lime and uric acid calculi were open to discussion from the distribution point of view. The stone-producing districts were practically confined to the north-west districts of India—namely, along the valley of the Indus and the upper reaches of the Ganges. Although these districts were wide alluvial plains, for the most part, the rivers rose amongst mountains of cretaceous formation and the impregnated waters of the rivers were carried down to the stone-producing regions. Climatic and meteorological considerations generally played, perhaps, an important part in the etiology of stone. In the regions described as affected extremes of heat and cold prevailed, and the non-flushing of the kidneys, during the hot weather, allowed of the deposits of crystals in the urine and developed in time into calculi. The relation of food and diet to the presence of calculi had been dealt with almost exhaustively by Sir William Roberts. He attributed the prevalence of stone in India to the fact that rice was largely consumed there; but in the districts where stone chiefly was met with wheat and barley were largely consumed. It did not seem, again, that eating flesh had anything to do with the formation of urinary calculi. The Mahomedans consumed flesh, but in Upper Bengal these people suffered from stone, while Mahomedans resident in Lower Bengal were almost entirely free from the complaint. Litholapaxy was the form of treatment which Mr Freyer recommended for stone Lateral perineal litho[illegible] practised in India Next [illegible] lithotrity (crushing the sto[illegible] been popular in India It [illegible] general that the excellent results in the treatment of stone were obtained and the mortality was reduced to a minimum To Lieutenant Colonel Keegan they owed the establishment of the practice of litholapaxy in the case of children—a practice which was now well nigh universally employed The question of the power of the native to recover from *operations had been advanced to explain away the excellent* results obtained by practitioners in India from litholapaxy and other operations Mr Freyer did not believe this statement and held that the European at home or in the tropics recovered as well as, if not better than, the native after major operations In India prostatic diseases were not met with to the same extent as in England the explanation of this being that the natives did not come to Europeans to be treated for p[illegible] 'catheter life' was almost [illegible] nts suffering from prostatic [illegible] in India and died more quickly from the complications induced

Surgeon General R HARVEY, C B, Director General of *the Indian Medical Service upheld Mr Freyer in his* opinions in favour of employing litholapaxy in India He had crushed calculi in India by the old lithotrity method at several sittings but on one or two occasions the patient ran away whilst but imperfectly cured The native could not understand many operations where one even lithotomy, got rid of the ailment at once By Mr Freyer's and Lieutenant Colonel Keegan's work not only India but surgery in every country had been advanced by the adoption of litholapaxy

Dr P MANSON F R S, did not consider that the presence of lime in the drinking water was sufficient to account for the prevalence of stone. The irregularity and capricious geographical distribution of urinary calculi seemed to be due to some other cause, and Dr Manson, arguing from the fact that the presence of a foreign body in the urine, be it mucus or the ova of bilharzia was known to occur as the nuclei of calculi considered that urinary calculi might have generally a parasitic genesis In many parts of the world stone in the bladder occurred in regions where lime was not present in the soil, as in South China and in Aberdeenshire

Lieutenant-Colonel G M J GILES I M S, considered that Mr Freyer had scarcely proved his point as to the source of stone in the north west part of India. Colonel Giles did not quite agree that the district in question was of the intensely calcareous nature stated by Mr Freyer The water in the wells of the district was by no means strongly impregnated with lime salts He was inclined to agree with the opinion of Dr Manson that a parasitic origin of stone would very likely be found to be usual were the matter fully investigated

Dr M F SIMON C M G (Singapore) said that except *amongst immigrants stone was practically unknown in the* Malay Peninsula. Rice fish and occasionally goat's flesh constituted the staple diet of the Malay, but he had never seen a Malay suffering from calculus during a 25 years experience.

Captain CHARLES MILNE I M S, stated that stone did not always prevail most in districts in which limestone was met with geographically

Dr L G HILL (Pakhoi China) remarked that at Pakhoi calculus was almost unknown whereas at Canton only 200 miles away and in the same province of China stone prevailed very extensively

Dr R U MOFFAT (Uganda) said that during 10 years residence in Uganda and East Africa he had found only one case of stone in the bladder There was no limestone in the Uganda district a fact which might favour Mr Freyer's theory The case he met with had a foreign body as a nucleus but he could not accept unconditionally Dr Manson's theory that all calculi had a parasitic origin.

Dr F M SANDWITH (Egypt) stated that in both Upper and Lower Egypt *the ova of Bilharzia very commonly formed* the nuclei of calculi The Nile water which constituted the drinking water of the Egyptians from its source to the sea passed through calcareous strata

Mr JAMES CANTLIE (London) gave personal experiences in regard to the practice of lithotomy and litholapaxy in Hong Kong He had difficulty during the performance of suprapubic lithotomy owing to the rupture of the indiarubber bag used to dilate the rectum just as the bladder was being opened Out of 54 cases of lithotomy two patients died and one of the deaths was from suprapubic lithotomy He had given up suprapubic lithotomy and believed that in a few years it would fall into disrepute as it had done during a previous cycle Litholapaxy presented difficulties in the more isolated parts of the world owing to the possibility of the lithotrite failing at the crucial moment. The indiarubber in the exhaust bottle also was apt to crack and leak and although litholapaxy was the preferable operation its practice in out-of the way parts of the world was at times attended by difficulties

Dust as a Vehicle for the Germ of Cerebro-spinal Fever

Major W J BUCHANAN, I M S, said that in a former paper on this subject he had related some 47 cases of cerebro-spinal fever and he now brought forward 13 additional cases, making 60 in all He observed that out of 60 persons in the central prison at Bhagalpur attacked by cerebro-spinal fever 57 were amongst prisoners engaged in dusty occupations The dusty occupations were brickfield work, road sweeping, &c and also wheat grinding rice-husking, &c The greatest number of cases occurred during the dry hot and dry cold months When respirators were given to the prisoners engaged in husking rice not a single case of cerebro spinal fever occurred amongst them, whereas in the previous season eight cases were due to working in dust of this kind Dust, therefore, would appear to be a frequent vehicle for the germ of cerebro-spinal fever

Lieutenant-Colonel GILES *stated that during an outbreak* of cerebro spinal fever in an Indian jail the symptoms in the first instance pointed to plague Colonel Giles agreed with Major Buchanan that cerebro spinal fever was more prevalent during the dusty season but he was inclined to believe that the disease had something to do with infection of the habitation

Four Cases of Abscess of Liver treated by Tapping with a Trocar and Cannula and Drained (Manson's Method)

Mr CANTLIE (London) gave details of four cases of abscess of liver treated by him during the past 12 months He had employed Manson's method in 28 cases in all up to date and 24 of the patients had recovered. The four recent cases were all intra hepatic cases preceded by dysentery Three of the cases recovered, the fatal case was that of a native of Zanzibar who was collapsed when admitted into the hospital and the operation was undertaken for the relief of symptoms merely Mr Cantlie advocated tapping by a trocar and cannula and the insertion of a large tube stretched on a metal rod through the cannula to the bottom of the cavity in all cases of deep seated abscesses Thereafter syphon drainage should in each case be applied and the cavity left to drain without either washing out or flushing The chief danger was the displacement of the tube as happened in one of the four cases owing to the patient becoming delirious Operation by the free method *—that was by laparotomy or by way of the thorax and pleura* with removal of a piece of rib—was in Mr Cantlie's opinion, unnecessary, over heroic and impossible when the surgeon was single-handed as he often was in the more isolated parts of the world Many patients objected altogether to "cutting" operations but readily submitted to tapping when the operation was explained to them In this way time was gained and both the practitioner and the patient would have less hesitation in the operation being performed on account of its simplicity When pus was close to the abdominal wall or bulging and œdema had occurred in the chest wall indicating that the abscess was quite superficial opening by the knife was almost free from danger but with deep seated abscesses the case was different and there was no shadow of doubt that Manson's method was by far the safest most easily performed and attended by the best results

Mr FREYER said that he adhered to the method of operation by incision and a free exposure of the cavity of the abscess He had given up the practice of using the trocar and cannula some time ago and he had no reason to *regret it*

Dr G P JORDAN (Hong Kong) stated that his colleagues and himself in Hong Kong had given up the operation by tapping and employed exclusively the free method He employed a silver drainage tube in preference to indiarubber and the results were very satisfactory

Dr W CHISHOLM (Sydney) said that in Sydney pus in the liver was almost invariably secondary to hydatids, and that the operation by incision was invariably followed. At the same time he regarded the operation practised by Mr. Cantlie with favour, as he was opposed to the rather heroic tendency to treat even minor ailments by major operations when a less severe method might suffice.

Captain W. R. BATTYE, I.M.S., reported several severe hæmorrhages in cases operated upon by Colonel W. K. Hatch, I.M.S., in Bombay, the result of deep punctures with a hollow needle. He thought such cases justified operation by the free method, one reason being that the hæmorrhage could be more readily dealt with when the bleeding surface was exposed to view.

Dr. MANSON said that he had seen operations by both methods and that in trans-thoracic operation many accidents were probable which could not exist when the operation was performed by the trocar and cannula. For deep-seated abscess he believed that the safest method was that by tapping and insertion of a large drainage-tube.

Mr. CANTLIE, in summing up, said that all of the speakers had recorded cases of superficial abscesses. He did not claim any advantage for tapping in cases of that kind—they mostly resolved themselves into merely letting out pus that was pointing; but that for abscess seated four or five inches from the surface operation by incision was difficult, likely to lead to hesitation to operate, and created unnecessary danger to life. Severe hæmorrhage during hepatic aspiration was due to puncture of the inferior vena cava. Were, however, penetration in proportion to the measurement of the patient's chest such danger need not arise. He had proved that in a chest of 32 inches circumferential measurement at the seat of operation penetration in a direction vertical to the surface should not be carried further than four inches.

NAVY, ARMY, AND AMBULANCE.

WEDNESDAY, JULY 31ST.

The Disposal of the Wounded in Naval Actions.

Fleet Surgeon G. KIRKER, R.N., opened this subject with a practical paper divided under three heads: (1) the surgeon's station, or the place where the wounded are treated; (2) the time of treatment; and (3) the conveyance of the wounded; and said that it had always been the custom to select some well-protected and easily accessible part of the ship for the reception and treatment of the wounded and to convert it before action into a special surgical station. In the old wooden battleship the "cockpit" or after-part of the orlop deck—a place below the water-line and approached by a wide hatchway—was universally selected as the surgeon's station, and many of the scenes which had occurred there had found their way into history and art. When the iron battleship displaced the wooden one the "orlop deck and cockpit" disappeared and naval surgeons lost their prescriptive station in action. Then the captain and medical officer selected the place they thought most suitable. In this way the location of the surgeon's station was settled and owing to variations of ship-construction it would be so settled until a proper modern operation-room or modern "cockpit" was fitted up. This operation-room should be included in the internal arrangements of every modern battleship and cruiser. It need not be large and it should meet the requirements of aseptic surgery. It need not be particularly easy of access for with a properly devised ambulance sleigh the wounded man could be easily and safely taken down and along all hatchways and passages. During peace important surgical operations could be done in the operation-room and valuable surgical instruments and necessaries could be kept there. In time of war the surgical accessories would be protected during action, and after action operations would be done with more chance of success than occurred in bath-rooms or greasy mess-places. The preservation of the lives of the surgeons and the safety of appliances during action would prevent such disasters as occurred on board the Japanese ship *Hiyei* at the battle of the Yalu. In this ship a shell entered the wardroom, in which the cockpit was located, killing surgeons, nurses, and wounded, and destroying all surgical appliances. With regard to the time of treatment, it was the rule in time of war to remove the wounded at once to the dressing station. In modern warships it would not be practicable to remove the wounded during action; they would be left to wait for a lull in the fighting. The Japanese found that the surgeons could do no really good work till after the action. M. Fontain, Médecin-en-Chef de la Marine de France, in a paper at the International Medical Congress, Paris, 1900, stated that in the French navy no treatment of wounded would be attempted. The men would be attended to as well as possible and restorative drinks would be administered, and after the action they would then be removed for treatment. In the matter of the conveyance of the wounded on board ship many contrivances had been used or proposed, but except the ambulance hammock and the ordinary canvas stretcher—which was mainly for use on shore—none had received official recognition. As far as he was aware this was also the state of matters in all foreign navies except those of France and Chile in which Auffert's gouttière métallique had been adopted. Among the contrivances in existence might be mentioned modifications of the service hammock (MacDonald), cot (Lloyd and Gonges), and stretcher (Dick), also Mowle's chair and Kirker's ambulance sleigh. An ambulance sleigh to be suitable for use on board ship should satisfy several important conditions. It should be able to retain its occupant securely in all positions from horizontal to perpendicular and it should be able to descend through a hatchway by sliding down the ladder if there was one, or by being lowered at any angle if there was no ladder. It should be short in order to get easily round corners, and in confined spaces where there was not room for two men to carry it it should be transportable by one. The speaker here showed some graphic photographs of the "sleigh" being used on ships of the Channel squadron.

The PRESIDENT (Deputy-Surgeon-General W. G. DON) commented in eulogistic terms on Fleet Surgeon Kirker's paper and invited discussion.

Fleet Surgeon C. L. VASEY desired to know whether any arrangements had been made on Fleet Surgeon Kirker's sleigh for special injuries such as fracture of the thigh, ankle, &c.

Inspector-General A. TURNBULL, R.N., said that the question of the transport of the wounded on board ship in time of war and in action had been the subject of consideration for years past. The sleigh was the most practical thing he had seen yet, and the only other thing was the St. John Ambulance Lowmore jacket which was good in its way. The surgical equipment during and after action was very different from that which was required in peace conditions. The appliances used in times of peace were quite unfitted for work during and after action and it was very difficult to go about properly equipped for an engagement which might occur at any moment most unexpectedly.

Surgeon-General T. F. O'DWYER, A.M.S., Principal Medical Officer, Aldershot, made some remarks on the value of antiseptic surgery and the benefits of settling on the space to be allotted on board ship to the care and treatment of the wounded.

Dr. LEIGH CANNEY (London) remarked that it was surprising to hear that on a complicated modern battleship no adequate and satisfactory means of transporting the wounded existed and he thought that the best possible scheme, such as this one suggested by Fleet Surgeon Kirker, should be adopted and put into use with the least possible delay.

Fleet Surgeon KIRKER, in reply, thought that the most important points to be borne in mind were those three points which he laid stress upon in the beginning of his paper—namely, the surgeon's station or place of treatment of the wounded; the time of treatment; and the conveyance of the wounded.

Surgeon F. H. A. CLAYTON, R.N., contributed a paper on the same subject which, in his absence, was read by the secretary. He advocated fore and aft operation-rooms, and dealt in detail with the arrangements necessary and the surgical appliances needful and imperative, and advocated the strictest possible antiseptic and aseptic precautions, even to dressing the crew before action in sterile garments. He commended hospital ships and careful training of ambulance parties.

The PRESIDENT made appropriate remarks on the careful attention to important detail.

Inspector-General BELGRAVE NINNIS, R.N., also contributed a paper on the same subject. He strongly advocated the use of special hospital ships to take off the sick and wounded. He also dealt with the internal arrangements of such ships and laid down special guiding rules as to their mission and construction. They should be floating hospitals, and the treatment of the sick and wounded should be their sole and only use They should embody all the essentials of a small and perfectly equipped land hospital, infectious fever cases excepted The propelling power should be arranged to leave ample space for wards, yet be strong enough to keep the ship within signalling distance of the fleet Her tonnage should allow of a lower deck partially below the water with port holes a middle deck, a main deck and an upper deck. She should be of steel or iron and wood cased on the outside for coolness Large doors should be in the ship's side for transport and a platform outside to act as a stage which could be hauled up against her side when not required Each deck should be cut off from the decks above and below Ventilation could be procured by shafts Each deck should be approached from the upper deck by a separate companion Lavatories and water closets should be provided for each deck and in the "companion space Wards should extend across the ship for purposes of through light and draught Beds and cots should be swung by short slings but they should be capable of fixation by iron stays Operation wards should be on the upper deck and near a lift well opening into the surgical ward The lift should be able to take a mattress of the same size as those used in the wards A special research room should be provided in the immediate vicinity of the operation ward separated from it by a space

The PRESIDENT made a few remarks, commending the suggestions of Inspector General Ninnis and invited discussion

Inspector General TURNBULL deprecated the complication of surgical arrangements and appliances, also a too great elaboration of detail in the arrangements of hospital ships, he advocated the provision of good ventilation and the facility of segregating infectious and other special cases He thought that the desired results could be arrived at in some such simple manner as that suggested by Lord Lister

Staff Surgeon W E HOME R.N, contributed a paper composed chiefly of statistical matter on

The Healthfulness of Modern Warships,

and emphasised the following points —The only source of information was the annual report of the health of the navy, early iron ships were by the experience of the training service shown to be healthier than wooden ships, the early central battery ships were healthier than the early iron ships, the turret ships were healthier than the central battery ships, shown by experience with Malta fever, the new first-class battleships now in the channel were healthier than were the old channel ships, and the best way to secure a healthy ship was to keep her well ventilated and dry

In the discussion which followed Inspector General TURNBULL said that the crews on wooden ships were subject to sloughing ulcer and infectious diseases usually spread like wildfire when once they obtained a footing on a wooden ship Cerebro spinal fever was not unknown in connexion with wooden ships

Fleet Surgeon KIRKER did not think that the sanitary conditions on board ship were all that could be desired chiefly because the necessary cubic space was not obtainable The greater the reduction of the ship's complement of men the better the health records became

THURSDAY AUGUST 1ST

The proceedings of this section were opened with a paper contributed by SIR WILLIAM MAC CORMAC, Bart., K C B, K.C V O to a crowded meeting entitled,

Some Remarks by Way of Contrast on War Surgery Old and New

He dealt with the position attained and yet to be attained in general estimation of the sterling merit of the medical officer of the army and quoted from McWhinnie's introductory address at St Bartholomew's Hospital in 1856 Colonel Ambert's touching eulogy of the military surgeon during and after battle He agreed with McWhinnie that the blame attached to the medical department of the army at the beginning of the Crimean campaign was due to non adoption by the authorities of their recommendations and when these injunctions were tardily attended to matters improved markedly The results of surgery in the Crimea far surpassed (according to Dr Balfour then of the Royal Military Asylum Chelsea) the anticipations of even the best friends of the department He compared the Peninsular, Crimean American and Franco-German wars with the South African war as to length of struggle, number of wounded and strain upon the Army Medical Department He said that in considering matters there must be taken into account the organisation of the medical corps the improvement in means of transport of sick and wounded the formation of hospitals and commissariat supply He mentioned the introduction of chloroform into field work and stated that Baudens mentioned it as being administered 25 000 times without a single fatal result It was more precious in the field than in civil practice Antiseptics were not employed in the Austro-German war and only to a slight extent in the Franco German war He next touched upon the mortality after operations and gave a list of the serious septic surgical accidents then prevalent after operation and mentioned the heavy mortality in fractures of bones and the great number of deaths from hæmorrhage He explained the bearing that the large bullet had on the increased mortality, and he mentioned Bergman's and Reyher's success in treating bullet wounds of the knee joint in the Russo-Turkish war In Egypt in 1882 antiseptic surgery prevented the occurrence of one single case of post operation sepsis as gangrene erysipelas, pyæmia In South Africa chloroform and morphia were universally used and gave blessed relief from much pain and suffering The modern bullet caused less shock and less injury to tissues Bone was damaged in a limited degree and recovery was generally rapid and without complication The bullet was aseptic did not as a rule carry clothing into the wounds and acted mainly as the producer of subcutaneous wounds therefore frequency of recovery was great Bullet wounds of the abdomen thorax head joints, spleen liver and kidneys were commonly less fatal than ever before known Large arteries were cut without any appreciable hæmorrhage In the Crimean and the Franco German wars deaths from hæmorrhage in the field were about 20 per cent, in the South African and the Cuban wars deaths from this cause were comparatively rare He did not advise interference with resulting arterio venous aneurysms unless complicated Non interference was what was found in South Africa to suit the majority of every class of injury, especially in abdominal cases He then compared the mortality from injuries occurring to various parts of the body in the various campaigns as the thigh the chest the head, the abdomen &c Amputations would be found to have been amazingly rare He next compared the relative numbers of killed and wounded in the South African war and those casualties occurring in previous wars. In the American war one man was killed for every four and a half men who were wounded in South Africa only one man was killed to every seven men who were wounded. From 6 to 8 per cent now died from wounds, in America 14½ per cent. died Sir W MacCormac next touched upon the causes of the small mortality in South Africa and he cited the lists of killed and wounded at Gravelotte St. Privat, Koniggratz Waterloo and Mars la Tour when the killed often exceeded 10 000 in a single fight and the wounded ran into tens of thousands On the other hand in South Africa, whereas at Colenso the Boers had five only killed and 25 only wounded we suffered a loss of 1100 casualties owing to the Boers not being seen and our men fighting in the open The casualties were surprisingly small in number He next dealt with the field dressings and commended the same in a qualified manner The Roentgen rays came in for well deserved prais

probe a cause of mu

account of the magn

for removing and attending to the wounded and the enormous distance in aggregate travelled by the hospital trains the great value of the hospital ship and he laid the greatest possible stress on the remarkable rapidity with which the wounded had been transported from the field of battle to places where every care and luxury had been provided He concluded a paper of world wide interest by a reference to the bad old days when the wounded were allowed to lie out on the field of battle to be robbed and murdered by thieves and cut throats among camp followers

The PRESIDENT characterised Sir William MacCormac's paper as being above comment or criticism and he said that the paper was a most remarkable vindication of the Royal Army Medical Corps in South Africa.

Dr ROBERT FARQUHARSON M P, also characterised the paper as being far beyond criticism The country ought to be grateful to Sir William MacCormac for his noble work his experiences and the recounting of them He agreed with the President that the paper thoroughly vindicated the Royal Army Medical Corps It was most ungenerous of the general public to have so treated men working hard on behalf of the suffering. He had asked on the floor of the House of Commons that the Government would speak some cordial words of thanks to the Royal Army Medical Corps as they fully deserved it. They had sent out a commission to inquire about the Royal Army Medical Corps but no commission had been sent out to inquire about the failures of generals and military departments; it seemed that the Jonah of the services was the medical department. That commission reported favourably, for it could not have done otherwise, and it was no packed or whitewashing commission, and to speak of it as such was an outrage and a scandal. The surgical skill displayed in South Africa was highly creditable to those employed. The favourable results of this campaign as regards medical skill in the treatment of wounds would impart confidence to the soldier and as a consequence, he knowing himself to be surgically safe if wounded, would, if it were possible, fight with greater pluck. He cordially hoped that Sir William Mac Cormac's paper would be widely circulated throughout the world.

Fleet-Surgeon G. KIRKER, R.N., said that in the Russo-Turkish war, in which he happened to have been employed through the kind influence of Sir William Mac Cormac, he came to the conclusion then that conical bullets would inflict less severe wounds than spherical bullets. He had put this on record and his prediction had now come true. In Turkey compound bullet-fractures of the thigh healed rapidly. Lung wounds were singularly rapid in recovery. He had seen knee-joints heal after injury without suppuration. Mr. Clinton Dent had brought forward the fact that the nature of the projectile was the real cause of the trivial character of the resulting course of the cure and not so much the use of antiseptic surgery as was commonly supposed, though the latter in great part contributed to a favourable result.

Surgeon-General T. F. O'DWYER, A.M.S., Principal Medical Officer, Aldershot, said that deductions by a master mind were what were wanted and Sir William MacCormac had given them, and that made his work so much the more valuable. At Waterloo 50,000 infantry had a front of three miles but in the advance from Bloemfontein rather less than that number had a front of 20 miles. This contrast involved a marked increase of medical transport. The antiseptic field dressing was a most important part of the equipment and every man was well instructed in its use. The medical department had found so much equipment that very little was left to supplement their efforts, as available material was exhausted. so that showed that they had done much good work.

Surgeon-General J. B. HAMILTON, A.M.S. (retired), gave a short account of the progress of the development and adoption of the conical ball. The Snider-bullet had not been used in fighting with the army. This was fortunate as the Snider-bullet would have been a most deadly bullet. Most fortunately for humanity it went out. He thought that the Dum-Dum bullet was a deplorable mistake of the Government for which we had been suffering a just retribution in South Africa. He gave the results of experiments on soft-nosed bullets recorded last year at the meeting of the section by himself. The Dum-Dum bullet caused injuries out of all proportion to what was necessary. The form of projectile was vital to humanity. The medical profession should press the Government to abandon the soft-nosed bullet. The Geneva Convention had condemned it and all found using it should be court-martialled and promptly shot.

Surgeon-Major G. K. POOLE, M.D., referred to the men who had come home from South Africa and noted that some had suffered terribly, whilst others made quite light of their injuries.

Surgeon-General R. HARVEY, C.B., D.S.O., Director-General, Indian Medical Service, said that during the last five years the first field dressing had been issued to the whole of the Indian army and had proved exceedingly valuable. The loss from wounds was very small indeed. He agreed that the Dum-Dum bullet should not be used against civilised troops, but when one came to deal with those of lower nervous organisation, such as savages, Soudanese, Ghazis in India, the Dum-Dum bullet was the only possible means of stopping a rush. It caused serious panic among civilised troops to see a man hit five or six times mortally through the body and after all come on and kill his man before he fell. In his opinion in war the main object was to "stop your man"; if one could not do so by injuring him then the next best means, even to killing him, must be adopted. Humanity, he thought, "began at home," and from his point of view it was far more humane to kill the "other fellow" before he succeeded in doing the like service for you, and that there was a limit to certain things no less in killing than in others, especially where certainty of means of doing so were involved.

Dr. J. W. SMITH (Manchester) said that from his experience in South Africa he agreed with Sir William Mac Cormac that the first field dressing was not as antiseptic or as efficacious as was supposed. It was the nature of the small bullet-wounds, the hot sun, and the clear dry air that caused the good results. Adhesive plaster should be used in the field dressing. He would like to bear testimony that the Royal Army Medical Corps, to whom he was temporarily attached, did their work splendidly in South Africa. He gave evidence before the Commission and he could truthfully state upon his honour that there was nothing upon which the Commission was not most fully informed from all quarters and under all circumstances. Especially at Bloemfontein was this the case, the fullest investigation being made.

Dr. F. C. H. PIGGOTT (Teignmouth) pointed out that the so-called explosive bullet was in reality an expanding bullet.

Surgeon-General R. HARVEY said that an explosive bullet was not used by us at any time, and they were only used by some sportive Boer who, having used them for game shooting, decided to use them on our men.

Lieutenant-Colonel G. M. J. GILES, I.M.S., said that Surgeon-General Hamilton's humanity might suit the native's point of view, but was not humanity for poor Tommy Atkins.

Surgeon-General C. SIBTHORPE, C.B., disagreed with Surgeon-General Hamilton on the matter of the Dum-Dum bullets against savages.

Sir WILLIAM MAC CORMAC, in reply, spoke eulogistically of the work of the Royal Army Medical Corps. He said that bullets not pills, according to Lord Kitchener, with whom he agreed, were what were wanted at Bloemfontein shortly after its primary occupation. This was not surprising, as the main consideration was war, and they must bear in mind that once upon a time the wounded were killed by their own people; nowadays they strained their resources to the utmost on their behalf.

Dr. LEIGH CANNEY (London) read a paper on

Air-borne Typhoid Fever in Armies.

He dealt with the water-supplies of various Indian cities and various outbreaks of enteric fever, and contended in a long paper containing much original work that water, and not air, was the main channel for conveyance of typhoid infection, and that air, dust, and flies were a comparatively weak medium. He reviewed sanitary matters in India and then dealt with the same in the campaign in South Africa. This was followed by an exposition on sanitation in Egypt, especially at the barrage works on the Nile, and on tourists' risks. He strongly advocated a special water corps attached to the Royal Army Medical Corps to care for the water-supplies of the army when in the field.

In the discussion which followed the PRESIDENT commented in favourable terms on Dr. Canney's paper and stated that for the most part he believed that typhoid fever was water-borne.

Surgeon-General C. M. CUFFE, C.B., said that he had had some returned enteric fever invalids from South Africa, and among them were men of the Northamptonshire Regiment who contracted enteric fever due, he thought, to sewer gas entering the barrack room from sewer pipes found to be defective. The urine of other patients who had recovered from enteric fever had been examined and the result was negative as far as the typhoid bacillus was concerned. The outbreak was, in his opinion, due to direct infection from the source mentioned, and he advised the authorities accordingly. He thought that flies were a great source of infection. The unsatisfactory army kitchen arrangements and defective cleanliness of the cooks were in great part responsible. Soldiers, on the other hand, would persist in drinking water labeled "not for drinking."

Dr. J. W. WASHBOURN (London) believed that there was some foundation for the air-borne theory. The Maidstone outbreak showed water-borne typhoid fever. There would also be in every epidemic direct infection of certain cases. such as occurred in Maidstone. He thought that dust did occasionally convey typhoid fever in South Africa, though it was not the main cause, for in summer in South Africa there was little dust and much typhoid fever. He therefore thought that typhoid fever was chiefly water-borne. He agreed with Dr. Canney as to proper protection of water by such a corps, as it would prevent epidemics.

Lieutenant-Colonel GILES, I M S, thought that flies and dust were some of the ways of carrying typhoid fever as well as water which everyone was agreed on was the main source of infecti a deadly and horrible source of fly due to the intermediary 'atrines and the food Removal two years kept down typhoid fever for that period. He thought that the Agra water supply was as good as was that even of London

Dr G E G SIMONS (Merthyr Tydfil) said that his experience as a medical officer of health entitled him to speak on the matter and that in his opinion, judging from results, typhoid fever was more due to flies than to water and to direct contamination. In a large epidemic he found that houses in one terrace the water supplied to which was *good and free from infection were always being attacked and* had been so for years past There were accumulations of manure and filth close by and the flies lived and bred there He cleared away the filth and the typhoid fever ceased He found here also that in summer and early autumn adults and children were affected, but that in winter children alone *were infected. When summer returned the typhoid fever in* adults did so also He found the soil near a surface drainage channel infected with typhoid bacilli which were cultivated from the channel and were afterwards used in Widal's reaction The children infected were those of a school age who played about the drain He thought that *the infection* reached the children direct and was transported to food by flies and thus affected the adults in summer In a case of two regiments near, and civilians, taking the same water supply the soldiers of one regiment which was without fly-proof cages for the food were the only persons attacked by typhoid fever, and the soldiers of the other regiment which had them, and the civilians, were not troubled with a single case.

Dr LEIGH CANNEY, in reply, said that the Royal Army Medical Corps ought to have a water corps He agreed with Dr Washbourn that the majority of cases were due to water

A discussion then followed on

The Organisation of the Military Services

The PRESIDENT deprecated the discussion at the present time as the matter was *sub judice* elsewhere

Surgeon General R. HARVEY agreed with the President but wished to state that the report of the Parliamentary Bills Committee had aroused unanimous disapproval and opposition in the Indian Medical Service throughout all India Though he sympathised with the Royal Army Medical Corps he did not approve of its rehabilitation being effected at the expense of the Indian Medical Service if the proposals of the committee's report were carried out He thought that the reform could be carried out in the Royal Army Medical Corps without interfering with the Indian Medical Service. The Indian Medical Service were quite contented with their lot and any grievances they had were minor and local and not of main service interest. The service should offer good prizes to good men—at present good and bad ranked together—attach a good allowance to station hospitals, and give them to good men The men should have plenty of practical experience in times of peace and leave for study and instruction He tried a scheme in India to put all men in Punjaub through a four months' course of practical surgical training in the hospitals He thought the military discipline should be removed from professional duties and that professional etiquette should take its place, men should not be ordered to change their diagnoses and thus stultify themselves, nor ought they to be compelled to ask leave to do a circumcision, or to give chloroform, or to avulse a toe nail Each man should be solely responsible for his case as in civil life He was emphatically of the opinion that the Indian Medical Service would be ruined by the interference suggested in the committee's report

Surgeon Major G K POOLE M D, also spoke

Inspector General A. TURNBULL moved that the further discussion of this matter be now forthwith closed This was seconded by the PRESIDENT and approved by the meeting

DERMATOLOGY

WEDNESDAY, JULY 31ST

The proceedings of the section commenced with an exhibition of cases, after which

The PRESIDENT (Dr J J PRINGLE, London) made a few introductory remarks

Dr RAYMOND J SABOURAUD (Paris), who spoke in French, read a paper

On the Role of Cocci in the Pathology of the Skin,

and said that there were three microbes of the genus "coccus" which played an important role in the pathology of the skin. The first was the streptococcus of Fehleisen the special cutaneous lesions produced by which was the impetigo contagiosa of Tilbury Fox. The second was the *staphylococcus aureus* of Rosenbach, the special cutaneous lesions produced by which was the follicular orificial pustule of the impetigo of Bockhart The third was a grey cultured staphylococcus (morococcus of Unna), the special lesion produced by which was pityriasis simplex wherever situated Apart from their specific lesions each of these microbes *might be accidentally found in other lesions* as a "secondary infection," by the evolution of which each might be modified in its own special pathogenic manner He was of opinion that the varieties of cocci invading the skin were much less numerous than was generally believed by Unna and others, and he thought it possible that the three kinds *of cocci* he was about to describe were quite likely to be polymorphic varieties of one and the same microbe

1 *The streptococcus*—The streptococcus which might cause a great number of general lesions might produce very diverse cutaneous lesions In the course of streptococcic septicæmia the bullæ of infectious pemphigus might arise In them cultures proved the existence of the streptococcus as in the different metastatic lesions of the visceral organs which it also caused. In the course of these infective states lumps might develop in the skin similar to those of erythema nodosum which were the result of streptococcic thrombi in the blood-vessels of the derma Direct inoculation of streptococci into the derma might produce erysipelas, characterised by the multiplication of the microbe in all the epidermic and dermic layers of the affected region. But the specific lesion which the inoculation of the streptococcus provoked in the epidermis was the impetigo contagiosa of Tilbury Fox It began by a flaccid bulla of very ephemeral existence, which yielded an enormous quantity of serous liquid This exudation dried up to form a yellow, scabby, adherent crust Under the crust was found a little fibrinous exudation characteristic of the multiplication of streptococci on the ulcerated epidermis The lesion disappeared without leaving any cicatrix. Streptococci very often occurred as complications of a great many diffused lesions of the epidermic surface (eczema) Their secondary multiplication reproduced the two capital symptoms—that is the diffuse exudation of limpid serum and the slight fibrinous greyish-blue exudation on the surface of the epidermis deprived of its horny layer The streptococcus might cause dermic ulcerations deeper than mere epidermic erosions—the rupia of Bateman These were conical ulcers with thin scabs containing a sanious liquid This lesion was now erroneously known in France under the name of "ulcerated ecthyma. The proper treatment of the streptococcic lesions of the epidermis was the local application of solutions of the sulphates—for example sulphate of zinc one gramme, aqua destillata from 100 to 200 grammes

2. *The staphylococcus aureus*—The specific lesions of the staphylococcus aureus was the pustule This intra-epidemic pustule was generally perifollicular Often it was deeper than the epidermis and produced a small cicatrix in the derma The perifollicular pustule contained groups of staphylococci under its corneal covering The cavity of the pustule was full of leucocytes and at its base was a point of dermic necrosis This pustule might extend in depth and thus cause a boil, a furunculous abscess, or a sycosis as the result of a deep multiplication of the microbes consecutive upon a superficial orificial perifollicular invasion These pustules might appear spontaneously (impetigo of Bockhart) or as the result of tiny traumatisms (dermatitis of hands of washerwomen) or after some medicinal applications (acne picea, pustular mercurial eruptions, &c.) In hairy regions pustular eruptions became very chronic, for example sycosis These pustules might be secondary to a pre-existing local necrobiosis. Thus both acne cheloid and acne varioliformis necrotica were pustules caused by the staphylococcus aureus originating round comedones The staphylococcus aureus might secondarily infect all lesions where the derma was exposed, either spontaneously (for example eczema) or accidentally (for example, vesicant applications) It might grow and multiply on lesions which it had not caused and might spread to evoke near them or even on them, its own special lesion, the follicular orificial

pustule with all the complications—boils, &c. These pustules, so abundant on the surface of chronic eczema, had been erroneously classed by Unna as the elementary and microbic lesions of eczema. It was easy when they met with a lesion containing the staphylococcus aureus to know if it were this microbe itself which had caused it, for in the lesions which it caused the staphylococcus aureus existed alone. Dr. Sabouraud then described the method of culture which he had employed. No microbic secondary infection could come after it. The local remedy for pustular lesions produced by the staphylococcus aureus was sulphur; for example: alcohol 30 grammes, sulphur precipitatum 19 grammes, aqua rosæ 100 grammes. It succeeded in all cases where the staphylococcic pustule was not superimposed upon a dermatosis in itself irritable or intolerant to its action, such as eczema.

3. *The grey cultured staphylococcus* (*staphylococcus cutis communis*).—This was the most common microbe on the surface of the human skin. It always occurred in single scattered elements. But on certain skins it found conditions propitious for growth. It then broke up the horny epidermis and caused pityriasis. In such lesions it did not exist as isolated elements, but in masses more or less considerable and numerous. It caused the fine pityriasis of the surface of acneic skins, the pityriasis simplex of the scalp or fatty pityriasis. This microbe caused cleavage of the horny cells of the epidermis which it raised by multiplying underneath them. It caused itching and mutiplication of the epidermic cells which result in the formation of scales—the elementary lesion of pityriasis. When its action was prolonged it caused a disturbance of the function of cornification which characterised the normal horny layer. Thus, the scale became fatty, the so-called seborrhœic "eczema" of Unna. When this multiplication took place on a dry skin the pityriasis, after having begun by a round spot, lost its regular form. When this multiplication took place on a previously fatty skin, its lesions kept their regular circinate form, as in the type which was called "circinaria" by Payne, "figurated seborrhœa corporis" by Duhring, "lichen annulatus" or "serpiginosus" by E. Wilson, and in France *eczéme parasitaire* (Besnier) or *flanellaire*. In all these pityriasic forms it was frequent to find near the grey-cultured staphylococcus the "fläschen bacillus of Unna" (spores of Malassez), which, perhaps, was only a degenerated form of the grey-cultured staphylococcus itself. When this special staphylococcus grew on a skin already infected by other microbes little pustules might accidentally form, which evolved almost without any functional symptoms. The most typical of these pustules was presented by the common little pustules of polymorphous acne. The best topical remedy against this microbe and for the pityriasis that it caused was coal-tar combined with the mercurial peroxide, oil of cade (juniperus oxycedrus) 10 grammes, yellow bioxide of mercury one gramme, yellow vaseline 30 grammes.

The address was illustrated by a large number of drawings and lantern slides from high magnification of microscopic specimens (up to 2000 diameters amplification) made by Dr. Noiret of Paris, under the direction of Dr. Sabouraud.

Dr. JAMES GALLOWAY (London) made a communication on the same subject. He commenced by remarking that the increase of pathological and bacteriological investigation in diseases of the skin had produced a large amount of information requiring criticism and simplification. The tendency had been to magnify small distinctions in organisms discovered, to consider these distinctions sufficiently important to characterise a species, and thus to introduce the organism as the specific cause of the disease. The streptococci and staphylococci had specially suffered from this tendency. It was to be recollected: (1) that these organisms were very variable both in cultural peculiarities and in virulence; (2) that inflammatory lesions of the skin were rarely the result of one cause or one pathogenic organism, but had a complicated causation, or at any rate were the result of mixed infections; and (3) on account of the enormous number and variety of organisms present bacteriological investigation was difficult and apt to be inaccurate and so to give rise to error. These results of his observations coincided with those of Dr. Sabouraud, and he (Dr. Galloway) was glad that Dr. Sabouraud had modified his views in some respects. There seemed to be three species of cocci specially concerned in diseases of the skin: (1) streptococcus, identical with the streptococcus pyogenes (Fehleisen); (2) staphylococcus—producing yellow cultures—identical with the staphylococcus pyogenes aureus (Rosenbach); and (3) staphylococcus cutis communis—producing whitish cultures—identical with the staphylococcus pyogenes albus (Rosenbach).

Dr. A. WHITFIELD (London) expressed a preference for Dr. Sabouraud's original classification of the cocci affecting the skin.

Dr. NORMAN WALKER (Edinburgh) thought it was remarkable that observers should be so anxious to prove that eczema was non-microbic. Pure streptococcic cultures could be obtained every time from impetigo contagiosa. He used agar first, then a fluid medium. The other two organisms found in the skin were the staphylococcus aureus and the staphylococcus epidermidis albus. He agreed with Dr. Sabouraud in the main.

Dr. T. D. SAVILL (London) wished to turn to the practical aspect of the question. He had inoculated a patient, a man, aged 27 years, who had been suffering severely for three months from boils, with some streptococcic vaccine, which Professor A. E. Wright of Netley had kindly supplied to him. The first inoculation was performed on a Monday, the second on a Thursday, and the third on Monday again. The patient made a very rapid recovery. This was perhaps remarkable because streptococcic vaccine (the dead cultures of streptococcus) had been used for what was known to be a staphylococcic infection.

Dr. W. DUBREUILH (Bordeaux) discussed the possible sources of infection in impetigo contagiosa: was it always a previous case, or might it not be any pus infection such as discharge from a suppurative otitis?

Dr. W. A. JAMIESON (Edinburgh) referred to the clinical aspect He thought it was curious that the same coccus should be the cause both of erysipelas and impetigo. He had seen extensive epidemics of the latter in schools, but not a single case of erysipelas had occurred.

Dr. H. RADCLIFFE CROCKER (London) referred to an infant who was recovering from vaccination complicated by impetigo. Six weeks later erysipelas developed which imperilled the child's life.

Dr. COLCOTT FOX (London) and Mr. GEORGE PERNET (London) followed.

Dr. W. DUBREUILH (Bordeaux) read a paper on

Paget's Disease of the Vulva.

Paget's disease of the nipple was first considered to be an eczematous condition of the skin which, owing to some local peculiarities, was liable to degenerate into cancer. Since then it had been proved that the disease was an epithelioma from the first, but a superficial one, attacking only the epithelial covering of the skin and lasting for years without invading the deeper structures. When it did go deeper it followed the epithelium of the milk-ducts. Paget's disease might exceptionally affect other parts than the nipple, but no case had been published of its affecting the vulva. The patient was a woman, aged 51 years, who had noticed three years before a tender part on or near the clitoris; this increased slowly and itched moderately. When first seen there was a large sore patch involving the front part of the vulva. The skin and the mucous membrane were superficially ulcerated, deep red, with a few white spots of thickened epidermis. The patch had a well-marked outline and was hard and thickened, so that it had somewhat the appearance of a syphilitic primary sore. The whole patch was removed, also an enlarged gland in the left groin. Microscopical examination showed that the epithelial covering of the parts was not destroyed, but had taken the aspect of ordinary epithelioma spread out as a sheet on the surface. The disease was quite superficial and the papillary layer of the corium was quite free. The epitheliomatous nests which were sometimes to be found deeper were easily traceable to the follicles and mucous glands, the superficial ulceration having followed down their epithelial covering.

Dr. J. M. H. MACLEOD (London) made a contribution on

The Histo-pathology of Yaws,

the material for which was obtained from the Kurunegalle Hospital, Ceylon, through the kindness of Sir William Kynsey, late Inspector-General of Hospitals, Ceylon. Eight typical cases of yaws in different stages of the disease were selected and characteristic lesions were excised. The tissues were preserved in spirit and for ordinary histological purposes were in no way injured by their journey from Ceylon. Yaws belonged to the group of the "infective granulomata." It was distinguished from (1) actinomycosis and rhinoscleroma by the absence of their specific micro-organisms; (2) from the lepromata by *the absence of Hansen's bacillus*; (3) from mycosis fungoides by the absence of "fragmentation" of the infiltrating cells, and of degenerative changes with the formation of products of degeneration in the collagen and elastin, and by the presence of the peculiar epidermal changes of yaws; (4) from tuberculosis, apart from the tubercle bacillus, by the absence of the characteristic architecture with its giant cells, daughter-plasma cells, more marked disintegration of the fibrous stroma, and complete disappearance of the blood-vessels; and (5) from syphilis it was distinguished by the following details which, considered collectively, strongly suggested that yaws and syphilis were different histological entities. (*a*) Cellular infiltration: plasma cells were not so definitely arranged in rows or clustered round the blood-vessels as in syphilis; no large multinuclear cells (chorio-plaques) or true giant-cells, or intracellular hyaline degeneration was noted in yaws. (*b*) *Fibrous stroma: rarefaction of the collagen* was more marked than in syphilis, but no organisation or colloidal degeneration (such as occurred in syphilitic gummata) was found. (*c*) Blood-vessels: there were no distinct proliferative changes in the vessel-walls or endothelium as frequently occurred in syphilis. (*d*) Epidermis: marked proliferation and down-growth of the epithelium, with a great thickening of the horny layer (due to hyperkeratosis or parakeratosis), were characteristic features of yaws, while they were unusual in syphilis.

Sir WILLIAM KYNSEY, C.M.G., F.R.C.P. Irel. (London), drew attention to the confusion between syphilis and yaws. The incubation of both was very much alike; in both there was polyadenitis. Superficially they much resembled each other but really they were quite distinct. The seat of inoculation of yaws was never sclerosed. The eruption was not polymorphic—it was always the same at all ages—and *essentially it was a non-ulcerative disease unless by pus* inoculation or tuberculosis. The constitution never suffered cachexia in yaws, and only the skin and mucous membranes were affected, not all the organs as in syphilis, and never the nervous system. Yaws was a disease of childhood, but it was *never congenital*. The eruption was a granuloma and it never left a cicatrix.

THURSDAY, AUGUST 1ST.

The meeting opened with an exhibition of cases by Dr. H. WALDO (Bristol), Mr. MALCOLM MORRIS (London), and Mr. JOHN HOWELL (Cheltenham).

Mr. MALCOLM MORRIS (London) then initiated a discussion on

The Treatment of Skin Diseases by Finsen's Light Method and X Rays.

He remarked that he would direct his attention chiefly to the application *of this treatment to lupus. In northern latitudes* the sun could not be relied upon altogether, and therefore the electric light must be had recourse to, which in point of fact was therapeutically more *active. In* respect of current he had found one of about 70 ampères and 60 volts sufficiently strong to produce the effect required in most cases, and it had been thought better to shorten the time of exposure rather than to lessen the intensity of the light. In order to get a powerful light it was *most important* (1) that the lenses, especially the bottom one, should be clean and bright and (2) that the water should be clear and free from floating particles. The bottom lens should be thoroughly cleansed and polished every day—a detail which was greatly facilitated by having it made detachable. The method of application was then described, and Mr. Morris remarked that up to July, 1901, the total number of cases treated at the *establishment under his direction* was 60. In 36 of these the disease was lupus vulgaris, in six lupus erythematosus, in 13 rodent ulcer, in one doubtful rodent ulcer, in two alopecia areata, in one cheloid, and in one epithelioma. Of the cases of lupus vulgaris eight might be claimed as instances of cure; in three the treatment was abandoned on account of failure of health, while *in six the result* was *unsuccessful or unsatisfactory*. The remainder were still under treatment. Of the cases of rodent ulcer seven were cured, in two the unsatisfactory state of the patients' health made it impossible to go on with the treatment, and two were still under treatment. Of the cases of lupus erythematosus in two the result was satisfactory, in three the treatment *had to be discontinued*, and one was still under treatment. Of the cases of cheloid and epithelioma nothing definite could yet be said. In the successful lupus cases the number of sittings *varied from* eight to 370. They were mostly favourable cases, in which the disease was superficial and of small extent. Brief notes of the cases were then given. Having stated the results which he had obtained, Mr. Morris proceeded to describe the manner in which the light rays produced their remedial effect on the diseased skin, and he mentioned some of the difficulties that interfered with their action. The application of the light was followed by an inflammatory reaction consisting in hyperæmia and redness, followed by the formation of a bleb which broke and dried in about a week into a thick yellow crust. Healing was complete in 10 days *or a fortnight. In places where the* tissues were loose—for instance, near the eye—there was often great swelling of the neighbouring parts. The intensity of the reaction varied in proportion to the intensity of the light and also according to the structural peculiarities of the patient's skin and especially according to the local conditions produced *by* the disease. In persons *with thin* skins the reaction was greater, while it was less marked in coarse thick skins. The reaction came on *from* five or six to 24 hours after the application of the light. It was usually slight at the beginning of the treatment and sometimes became greater as it was continued. Even after prolonged treatment it still showed a tendency to increase rather than to diminish. The Danish physicians said that the treatment was painless, but this was not strictly accurate. There was, indeed, seldom anything that could be called pain at the time the light was applied, though sometimes *a feeling of heat was experienced. But the after-smarting* was often considerable, and the inflammatory phenomena constituting the reaction were also more or less painful. There was seldom any constitutional disturbance. In the case of ulcerated surfaces there was, of course, no blistering or crusting; a much larger number of consecutive applica*tions could therefore be made without inconvenience* to an ulcer than to an area of intact skin. Reaction was manifested by redness and soreness which were sometimes accompanied by some swelling of the surrounding parts and great tenderness on pressure. These effects were seen about *the fourth or the fifth day, and if the applications* were kept up the skin around the ulcer became inflamed. According to Mr. Morris's experience the remedial effect of the light rays was directly proportionate to the intensity of the reaction; the production of a considerable reaction should, *therefore, always be aimed at*. If the disease extended into the deeper layers of the skin, and if there was much scarring, this formed an obstacle to the penetration of the light rays. Another circumstance which made the passage of the rays increasingly difficult when the treatment was prolonged was the pigmentation caused by the frequently repeated applications of light. The amount of pigment naturally present in *the skin must also be taken into account. Brunettes were* not such good subjects as blondes, and the darker they were the less amenable were they to the light treatment. Hence *there were great difficulties in applying it to patients of black* or mixed race. When the disease extended deeply and there was great thickening and infiltration of the tissues—e.g., from previous treatment by other methods—it was difficult for the light to penetrate and a large number of exposures were required to make an impression on the mass of diseased tissue. The large extent of the area involved was sometimes a most serious difficulty, as only a small spot could be treated at a time, and thus it was scarcely possible to deal with all the nodules as they developed on the edge of the patch. The only hope of keeping pace with the disease in such cases was to retain the patient under treatment two or three hours daily. This was seldom possible as the patient could not spare the time or tolerate the prolonged immobility required. Moreover, the reactions tended to become so severe that they could not be borne. Cases in which mucous cavities were involved were unfavourable for the light treatment, but in such cases x rays were useful owing to their power of penetration. If the disease were extensive the treatment must at the best be tedious. It should be applied daily on six days a week if there were nothing—as, for instance, excessive reaction—to make interruption necessary. In cases where there might be a special urgency the treatment might be carried out twice a day without any ill effect. Mr. Morris remarked that the success of the light treatment depended more on the attendant who had the actual management of the details than on the medical man who had the supervision of the case. Her duties required not only intelligence or skill, but devotion, for the work placed an enormous tax on the patience. Another condition of success was in the patient himself, to whom the absolute passivity enforced during an hour or one and a half hours daily for months together was apt to be exceedingly irksome. The length of time over which the treatment had to be prolonged was, indeed, one of the chief drawbacks of the method.

Dr. A. **BARRY BLACKER** (London) in continuing the discussion, said that he wished to compare the Finsen's light and x-ray treatment as regards their relative effects. The original light apparatus of Finsen was well known, but a modification which was now being extensively used in the treatment of lupus had been introduced by Dr. Lortet and Dr. Genoud of Lyons which was cheaper and more convenient, and which employed less current. Moreover, the exposure was only 15 minutes instead of 60 minutes daily, and the results from this apparatus were so far very satisfactory, but time must elapse before it could be proved to be equally efficacious. Dr. Blacker was now in his own practice employing both Finsen's and Lortet and Genoud's apparatus, using them both on the same patch daily, so as, if possible, to obviate in some measure the tediousness which was one of the drawbacks of this form of treatment. A comparison was then made between the reactions observed between Finsen's rays and the x rays on the skin; in the former case it occurred in from four to 24 hours, in the latter in from four to 24 days; the first was comparatively slight and easily controlled, the second was sometimes severe and an ulcer might be produced which might last for months. He wished to emphasise the fact that there was a definite danger of producing this intractable form of ulceration after the employment of the x rays. This could in some measure be guarded against by the employment of a "high" tube, by the protection of the surrounding skin with lead foil, and by watching with care the effect of short exposures on the patient. The reaction was more severe in fair people, in those who suffered from an irritable skin, and in neurotic individuals. In many cases, however, it could only be attributable to an idiosyncrasy. The action of the x-rays on lupus vulgaris was often very marked and was apparent after a few applications, sometimes, however, it was slow, and it was interesting to note that occasionally other patches of lupus than those which were being treated improved at the same time although they were not immediately under the influence of the rays. In the removal of superfluous hairs the action of the x rays was doubtful, as in all the cases in which he had seen the hair removed it had returned within the following six months; in tinea tonsurans it might be found useful. In the treatment of the pain accompanying ulceration he had found chloretone and orthoform of service. In conclusion, Dr. Blacker said that there was much to be learned about the treatment of skin diseases by means of light; especially was this the case as regards the employment of the x rays, which would appear to be a mixture of many kinds of light, some of which might produce harm. The difference between the action of rays from the violet end of the spectrum as employed with Finsen's apparatus, and the rays emanating from an x-ray tube were very marked; they differed in the reaction produced on the skin, in their penetrative power, in their mode of production, and in their employment. As regarded the rays, either from the sun or from the electric arc lamp, he considered that the results obtained in the treatment for lupus were sure and that they gave excellent results. On the other hand, he considered that much more had to be proved before the x rays could be considered as being safe or reliable.

Dr. J. H. **SEQUEIRA** (London) from an experience of 15 months' work at the London Hospital, where there were three lamps continually in use and where nearly 200 patients had been under treatment, had observed improvement in every case of lupus vulgaris. Cases of every degree of severity had been treated. In two instances where the disease was quite recent two applications had resulted in absolute disappearance of the lupus. In other and more extensive cases 200 and even 300 sittings had been given and the patients were still under treatment. He had found it very difficult to determine exactly when the treatment could be stopped with safety, and had seen cases [illegible] small recurrences had occurred. These were, however, [illegible]. Dr. Sequeira quoted the latest statistics of [illegible] in [illegible], mentioning that over 130 patients were [illegible] free from recurrence from one to five years after [illegible] In lupus erythematosus a certain proportion of cases did well, but in others there was no improvement at all. Those in which the erythematous element was very marked were particularly unsuitable. Dr. Sequeira then demonstrated his new lamp, modified from that of Lortet and Genoud, which was easily worked from an ordinary street service, and the manipulation was so simple that the great expense of the Finsen treatment could be materially lessened. Moreover, the sittings were of a quarter of an hour's duration only, and an area of skin one and a half inches in diameter could be treated at each sitting. Referring to the relative value of the Finsen and x-ray treatment, Dr. Sequeira had found that ulcerative forms of lupus yielded excellent scars with x-ray treatment, but in the scars typical lupus nodules were visible even when the treatment had been carried on for several months. He indorsed Mr. Malcolm Morris's experience of the value of x rays in lupus of the mucous cavities. Since his first case in June, 1900, he (Dr. Sequeira) had treated 45 cases of rodent ulcer with the x rays. The ulcers healed up rapidly and huge cavities filled up in a remarkable manner. Difficulty was experienced with the hard raised edge, and slight but easily treated recurrences had been observed. In his small experience of the treatment of cancer by the x rays he had found pain to be relieved and ulceration to be dried up, but in some cases the tumours grew rapidly in spite of the rays. A single case of nodulated leprosy of the skin had shown a marked improvement, the hard masses softening and becoming flat. The value of the x rays in diseases of the hair, especially sycosis, was commented upon, and the results achieved were regarded as being very satisfactory.

Dr. **ALLAN JAMIESON** (Edinburgh) remarked that his experience was limited to the x rays. His results had been very unsatisfactory in lupus vulgaris. Some paling but no cure had followed. In rodent ulcer he cited one superficial and extensive case which had been all but cured by the x rays combined with scraping. In another ulcer the nasal bones were involved, while in one part the disease was arrested; in another the ailment progressed in spite of, and while under, the rays. He regarded the rays as valuable means auxiliary to other and tried methods, but he could not see what advantage was to be derived over and above scraping, the use of the knife, and caustics.

Dr. H. A. G. **BROOKE** (Manchester) remarked that his experience was somewhat limited. He had been to Copenhagen and it was perfectly obvious that the results were infinitely better there than any which ensued from ordinary methods; the skin was healthier, smoother, and softer, and altogether he knew of no other therapeutic measure which could produce the same results. In a great many cases the disease started in the laryngeal duct, and it was absolutely necessary to reach this focus of disease to prevent recurrence. Finsen rays were not subject to the same dangers as the x rays, and he believed in the combination of Finsen and x rays as being the most efficacious, the latter being employed for the less accessible foci.

Dr. **NORMAN WALKER** (Edinburgh) was quite sure that in lupus vulgaris other foci of disease than those directly exposed to the light improved—e.g., those on the back while the face was being treated. He had in one case of lupus erythematosus had the most violent reaction, but the patient had undoubtedly improved in spite of this. As to favus this was in his experience a method which was quite unapproached. In one case he had had a patch on the scalp which very nearly sloughed. In tinea tonsurans he had not had very favourable results. In sycosis it was sometimes very favourable but at the cost of much tribulation to the patient. He thought it a pity that all other methods of treatment should be absolutely excluded. He had recently seen a case scraped 15 times which was most successful; and the galvano-cautery, acid nitrate of mercury, and the knife might be most important additions to the Finsen and x rays. The x rays should certainly be kept in the hands of the medical profession, and he wished to sound a note of warning in this sense. A form of quackery was arising which should be damped down at its inception.

Dr. G. G. **STOPFORD TAYLOR** (Liverpool) had employed x rays for the treatment of 22 cases of lupus, one case of scrofuloderma, five cases of rodent ulcer, one case of large ulcer of the left forearm after burns, one case of favus, two cases of epithelioma, and one case of pigmented carcinoma. As regards lupus vulgaris, he had observed, first, that when the rays were applied to a moist surface the discharge was lessened and became altered in character, assuming a purulent in place of a serous appearance; secondly, that normal epithelium developed very rapidly and healing quickly followed, thirdly, that when applied to dry surfaces exfoliation of the epidermis took place and the part exhibited a dried and shrunken appearance, fourthly, that absorption of morbid products took place and resulted in a smooth, soft, and pliant scar, and fifthly, that an erythema of uncertain duration depending not altogether upon the length of exposure or on its strength always accompanied these changes, and that unless this was permitted to disappear between each successive application of the rays an aggravation of the disease occurred. This had happened in two instances in his experience, and superficial destruction of tissue took place in three cases as if an escharotic had been used Too much had been expected from the x rays in the treatment of lupus He considered their action to be of the nature of a stimulant, and that they should be applied as such, care being taken that over-stimulation did not occur Any treatment of tuberculosis must of necessity prove tedious With a view, therefore, to accelerating the action of the rays he had not hesitated in a few instances to employ in addition any other means which seemed requisite, and the result was most encouraging While he had been able to remove all traces of secondary inflammation in some cases he had not succeeded as yet in causing the total disappearance of the characteristic apple jelly nodules The cases treated were not selected Many of them had been under his care for years and some had undergone various operations, such as curetting, cauterisation, scarification, excision, and the injection of tuberculin, but under no treatment had he observed the same steady and painless tendency towards recovery as under the x rays The effect of the rays upon that form of rodent ulcer which had a natural tendency to heal in one part while it spread in another had been a perfect revelation and cases were quoted in illustration He had succeeded in removing most of the hair off the scalp of a lad suffering from favus, but the presence of the fungus was still in evidence. He had noticed that the rays had the power of exciting the rapid development and temporary growth of epithelium even upon the surface of carcinomatous ulcers though the pigmented tumour cells could be clearly discerned through the new epithelium In further proof of the remarkable effect of the rays in stimulating the growth of epithelium the case was quoted of a boy who had sustained a severe burn of the arm, where any healing had taken place the scar was hard and fibrous and the prospect of a very troublesome contracture looked ominous The x rays were applied and the remaining part of the ulcer healed up rapidly with a soft and pliant scar, and the child had now a serviceable arm with a good movement

Mr J **HALL EDWARDS** (Birmingham) remarked that he had been obliged to discontinue the researches which he had commenced into this subject two years ago on account of his absence in South Africa He thought that it was greatly to be regretted that no light had been thrown upon some of the most important points From an examination of the interesting cases exhibited he had noticed that the same pigmentation which he always looked for during his treatment with the x rays occurred in cases treated by the Finsen light He had hoped to have heard more of the theories which were to account for the phenomena produced, and he felt disappointed at the little progress which had been made in isolating the cause of the curative and that of the hurtful, effects produced by the x rays He had previously stated that in his opinion the effects were to a great extent electrical, and more especially those which had any therapeutic value That some of the effects were due to the x rays or to some other rays which proceeded from an x ray tube he was certain, but they could not make any true progress until experiments enabled them to isolate the electrical from the purely x ray effects What condition of tube was best suited to the treatment? It had been stated that the x rays encouraged the growth and multiplication of the tubercle bacilli Was it not possible that their rapid multiplication under the influence of the x rays might bring about their ultimate destruction?

Dr **GEORGE B BATTEN** (London) advocated the use of the high tension tubes He believed that the x rays acted by stimulation of the healthy tissues and cells of the part and by over stimulation of the microbes which were so to speak, "grown to death"

Dr J S **BOLTON** (Nottingham) asked what was the cause of the cure. The high frequency current produced many of the effects of Finsen and x rays, and it would, he believed, prove to be of great value

Dr **RADCLIFFE CROCKER** (London), in closing the discussion, congratulated the speakers on the accuracy and completeness of their remarks He had had more experience of the Roentgen rays than the Finsen light, and had had some most excellent results He had come to the conclusions, first, that in the favourable cases the results were as good as it was possible to achieve, but, secondly, that the number of such cases was not very large The treatment must be limited in its scope owing to the expense and complexity of the apparatus, and when it was borne in mind that some cases wanted 300 sittings the applicability of the treatment must necessarily be limited But the Finsen and x rays treatment had evidently come to stay Nevertheless, it would be a great mistake to abandon the older and still excellent methods He referred to a case in which Mr George Pernet had performed multiple scarification in which the results could not have been surpassed. He (Dr Crocker) had worked with Roentgen rays, chiefly with low tension tubes, and he could not agree with Dr Batten in the advocacy of high tension The excitation of a small amount of inflammation was not altogether a disadvantage Something like five ampères was, he believed necessary The real practical difficulty was to know the number of exposures necessary, one case would require 80 and another 24 exposures The expense was an obstacle A case could be scraped and while healing could be exposed to the rays Some cases wanted one treatment and some another and they must not limit themselves to one kind of treatment

THE ANNUAL MUSEUM.

(Continued from page 3[illegible]1)

II.—FOODS AND FOOD PRODUCTS.

There was an excellent display of special foods, although it must be admitted that novelties were rather the exception than the rule Indeed it is pretty safe to say that at least, and probably more than three fourths of the exhibits in this section were but a repetition of the display at Ipswich last year There were however some notable exceptions, especially amongst milk and meat preparations Milk and milk products were decidedly in evidence Attention seems to have been devoted more particularly to the separation of proteids from milk in the form of soluble dry white powder The evidence in favour of plasmon as a highly assimilable and nutritious "additive" in diet continues The company's representatives (International Plas[illegible] quare London, W.) [illegible] the number of usef[illegible] [illegible]yed Amongst other things iced plasmon is worthy of notice Another preparation of importance is the plasmon beef extract containing 80 parts of plasmon and 20 parts of beef extract, representing the nutrient properties of milk and the stimulating properties of meat Besides these there were plasmon cocoa, biscuits and chocolate The Aylesbury Dairy Co., Limited, of St Petersburg place Bayswater London, W., may lay claim to have presented a demonstration of a decidedly scientific character Thus the rapid estimation of fat proteids and other constituents of milk was practically illustrated and other subjects practically discussed were the curdling of milk and the rapid estimation of acidity and the microscopic detection of the bacillus tuberculosis Further useful demonstration was given on points connected with the chemistry of milk The exhibits included a number of preparations of milk for invalids and infants As is well known the Aylesbury Dairy Company practise a system of control in connexion with all departments of their enterprise Their laboratory staff consists of 15 medical officers six veterinary surgeons and three analytical chemists As an example of milk produced in a thoroughly healthy way may be mentioned the germ free invalid milk and the germ free [illegible] mothered milk exhibited by Mr J Carson of Crystall [illegible] Farm Theydon Bois Essex His farm is a model of sanitary efficiency and medical men who are interested are invited to inspect this farm and see for themselves how cleanly the production of milk can be carried on We have recently had occasion to examine this milk and the results were highly satisfactory and such as would account for the remarkably favourable results which it gains when used in the feeding of infants and invalids The specimens exhibited showed a remarkable percentage of cream. The milk is derived from a special herd of Jersey cows, each of which is periodically inspected and examined. A very interesting and elegant milk product is casumen, shown by Prideaux's Pure Casein and Life Food Co., Limited, of Motcombe, Dorset. This is pure milk casein quite soluble in water. It occurs in the form of a fine white powder, and as our analysis has shown, contains over 90 per cent. of pure proteid. This preparation seems particularly well adapted for raising the nutrient value of many foodstuffs. It produces an excellent bread of uniform texture which keeps agreeably moist. Similarly it may be mixed with cocoa or put in tea or coffee or beef-tea or soup. Specimens of macaroni were shown containing a definite proportion of casumen. Pure casein preparations were also shown on the stall of Messrs. Callard and Co., of 25, Regent-street, London, W., whose diabetic foods are well known. Amongst other special foods shown by this firm were the celery and spinach biscuits prepared for the use of sufferers from gout and rheumatism. The Protene Co. of 36, Welbeck-street, Cavendish-square, London, W., presented a number of preparations containing protene. Amongst these may be mentioned protene biscuits, protene bread, and protene flour. Protene bread for diabetics is a good preparation containing a quite unimportant quantity of starch. The Manhu Food Co., of Liverpool and of 88, Charing Cross-road, London, W.C., exhibited a number of so-called diabetic foods, and the Cheltine Foods Co., Limited, of Cheltenham, showed a similar series of food specialities. Both companies appear to claim the same thing—that is, that the starch has been so treated as to become modified and no longer producing glycosuria. These views are opposed to the opinions of leading authorities on the subject. We welcome the departure introduced by the Myosin Albumin Meat Extract Co., of 107, Strand, London, W.C. It cannot be too widely known that the majority of meat extracts do not contain the nutrient properties of beef, but merely the extractives, which at their best are only appetising and stimulating but not nourishing. Myosin albumin is prepared in such a way that the albumins, globulins, and iron albumins are preserved in it intact as they exist normally in beef, while the coarse fibroid matter of beef is completely rejected. The preparation known as "ma.me.co." is described as consisting of pure myosin albumin from which the extractives, waste, or "gouty" products have as far as possible been removed. The preparations are of undoubted nutrient value and represent a step in the right direction towards making beef preparations of real food value. We have noticed before the table-salt known as "Cerebos," prepared by the company of that name of Newcastle-on-Tyne. It is a great improvement on the deliquescent salt which was exclusively used formerly for table purposes. Messrs. Keen, Robinson, and Co. of Garlick-hill, Cannon-street, London, E.C., exhibited their well-known preparations. Amongst these may be mentioned mustard prepared from the best seed, Robinson's patent barley and patent groats, and, lastly, "barlikos," a preparation of barley flavoured with lemon which makes an excellent and wholesome summer drink. The stall of the Bovril Co., Limited, of 152 to 166, Old-street, City-road, London, E.C., was covered with a great number of special foods now connected with their name. We did not notice any new additions to their already long list of meat preparations. An interesting food preparation, and one that deserves more attention than has hitherto been give to it, is marvis (The Patent Fish Food Syndicate, Limited, Berry Yards, Greenock), which may be described as a fish flour. It is said to be prepared from freshly caught fish, it keeps well and has a good flavour, and makes excellent nourishing soup. Liebig's Extract of Meat Co., of 9, Fenchurch-avenue, London, E.C., exhibited their well-known preparations, including lemco, a concentrated extract of beef, oxo, "a new meat beverage" containing a special preparation of fibrin, and peptarnis, a valuable preparation, being a concentrated peptone of beef. We could find no new preparations on the stall of Mellin's Food Co., Limited, of Marlborough Works, Stafford-street, Peckham, London, S.E., although the cod-liver oil emulsion and the lacto-glycose are worthy of mention. Some interesting preparations were exhibited on the stall of the British Somatose Co., of 165, Queen Victoria-street, London, E.C. Somatose is made from beef and, as we have shown, consists largely of albumose with some peptone. This valuable food preparation may now be had in fluid form and it is also combined with iron, forming a soluble digestive iron albumin. Messrs. Cadbury Bros., of Bourneville, near Birmingham, still claim for their cocoa that it is a pure article and entirely free from foreign additions, such as alkalies, kola, malt, and hops, a statement which we have entirely confirmed by laboratory experiment. An excellent substitute for lard for cooking purposes is albene, a highly refined vegetable fat prepared by Messrs. Broomfield and Co. of 83, Upper Thames-street, London, E.C. It is a clean white fat well adapted for frying and for pastry and does not turn rancid. In our analytical columns we have already shown that the shredded wheat biscuit (Shredded Wheat Co., 6 and 8, Eastcheap, London, E.C.) contains the entire wheat, and this fact, coupled with the further important fact that it is thrice cooked, makes the preparation a valuable food rich in flesh-forming as well as bone-producing factors, proteids, and phosphates. Messrs. Cosenza and Company of 95, Wigmore-street, London, W., showed their excellent Maggi's consommé and Maggi's tonic bouillon containing assimilable iron. We have already analysed and tried these preparations with satisfactory results. The only example of condensed milk shown was that of Mr. Henri Nestlé of 48, Cannon-street, London, E.C. As we have previously pointed out, one very important feature of this preparation is that it contains a maximum of cream. At the stall of Mr. Hoff, of 29, Newgate-street, London, E.C., besides the well-known nourishing fluid malt extract, was shown a preparation known as "ironol," containing iron in an organic form. A valuable series of special foods was presented to view by Messrs. G. Van Abbott and Son, of Baden-place, Borough, London, S.E. These were their well-known gluten bread, soya bread, biscuits, cakes, and every conceivable form of food adapted for the diet of the diabetic patient, being practically starch free. The exhibit also included some excellent soups, meat lozenges, beef biscuits, and hypophosphite of lime biscuits. The Maltine Manufacturing Co., Limited, of 24 and 25, Hart-street, Bloomsbury, London, W.C., exhibited their well-known maltine preparations. Maltine is a thin, syrupy, powerful starch digestive and may be had associated with cod-liver oil, coca wine, cascara, hypophosphites, Easton syrup, &c. Messrs. Carnrick and Co. acted in conjunction with the Maltine Co., their address in London being the same. They showed their liquid peptonoids with and without coca, beef, milk, and digested gluten. Their exhibit included also beef peptonoids, a very rapid form of nourishment and containing a very high proportion of nutritive material, and, lastly, Carnrick's soluble food for infants, consisting of evaporated cow's milk with the addition of dextrine and soluble starch. Messrs. Brand and Co. of Mayfair Works, Vauxhall, London, S.W., showed their well-known specialities for invalids, including meat juice, peptones, meat essences, and lozenges. Their exhibit was much the same as in previous years, though we may notice that they have comparatively recently added a nutrient powder dried in such a way as to leave the proteids uncoagulated.

(*To be continued.*)

THE COMING ELECTION OF DIRECT REPRESENTATIVES TO THE GENERAL MEDICAL COUNCIL.

THE meeting arranged by Mr. T. Garrett Horder with the permission of the British Medical Association for the discussion of the question of the election of the Direct Representatives and to hear addresses on medical politics from the present Direct Representatives for England and Wales took place at the Ladies' College, Cheltenham, on August 2nd. Mr. Garrett Horder was in the chair, and called first on Mr. George Brown.

MR. GEORGE BROWN said: I do not see that we can regard this meeting as one that can come to any definite conclusion by way of deciding as to who should or should not be recommended to the constituency as those who should be selected for representation. I should have preferred that some programme had been drawn up or some hint as to what would have been expected of me. Am I to give an account of my stewardship? If so, I am not prepared for that, except that during the time I have represented you I have endeavoured to carry out the programme on which I came before you as a candidate and on which I was successful in 1896. I hope that I have succeeded in satisfying those who placed me in that position. I have received no complaint from anyone about any vote I have given on the Council. On the contrary, I have received numerous letters from all parts of the country expressing approval as well as letters from different associations. I have reason to believe, therefore, that my stewardship has not been altoge[illegible] to those who sent me to the General Medical [illegible] am *not egotistical in* [illegible] election is justifiable [illegible] There may be people who say, and very often the remark has been made of me, that "Brown has a nice fat thing, his fees for the General Medical Council are 5 guineas a day." All I can say is that if it were only for anything of that kind I should wash my hands of the whole matter and should proceed no [illegible] a poor [illegible] which [illegible] out to [illegible] putting your hand in your pocket. I may mention that my midwifery practice has absolutely gone. In my practice the 50 cases in the year I used to attend have dwindled down to one, *and in that one I could not accept a fee because it was a domestic* [illegible] of one of the [illegible] oppose the [illegible] opposed it [illegible] a partially educated woman after three months' education should be given a diploma or *licence* to practise midwifery and be allowed to use dangerous drugs which they are advised to do by those who lecture to them. I have seen a lecture by a midwife to midwives in which it was stated that treatment had been carried out in a bad case of phlegmasia dolens without any mention being made in that lecture of a medical man [illegible] I think that that is likely to occur very [illegible] Bill is passed. You do not want me to [illegible] resolution will be put before you [illegible] to on the ground that the meeting is not representative enough. I will now refer to an incident which occurred during my last candidature. I was invited to a meeting at *Manchester*, and some notice was taken of a *remark of mine* then that if I remained on the Council for three years without something being done that I would resign my seat. I did not resign my seat at the end of three years because I found that your sending as [illegible] to the Council men from your own body had a [illegible] on some important matters on which [illegible] is shown by the salaries which [illegible] Five years ago medical men almost went down on their [illegible] " or [illegible] two [illegible] and [illegible] eral [illegible] t the [illegible] oeful [illegible] On another point I had a mandate, [illegible] tion, and a great deal has been [illegible] ough the effect is not very apparent [illegible] to which will have a great influence [illegible] candidates to the medical profession. [illegible] preliminary education exacted and [illegible] t on the future of the profession [illegible] urriculum has had a good effect in [illegible] men who were not perhaps so well [illegible] There is, however, still much to be [illegible] it road and in the course of time we [illegible] of you desired to have been done [illegible] t despaired of seeing accomplished. [illegible] have had others speaking previous [illegible] perhaps, then have had to answer [illegible] anticipate by saying what I have to say with regard to that unfortunate instance which has occurred during the time in w[illegible] I refer to the case of Kingsley Hu[illegible] myself from all blame entirely in t[illegible] stand the true facts of the case you [illegible] colleague Mr. Horsley of any blam[illegible] n is asked for are submitted to th[illegible] report to the General Medical Council. When the prosecution of Hunter was decided upon his name was dovetailed in in a list of men who were *practising without any qualification*—that is to say, *quacks*. All these names were put together and I have the written evidence of some members of the General Medical Council that when Mr. Hunter's name was dovetailed into this list of quacks not one of us knew that this man Hunter was a qualified man. Had that been known I, of course, should not have consented to his prosecution, and it was *with the greatest amazement that I saw many months afterwards* that by order of the General Medical Council this unfortunate Mr. Hunter had been prosecuted for taking a medical title. I am sorry this has occurred, but personally I do not have it on my conscience that I was guilty of any dereliction of duty in regard to that matter except that I might have called for all the evidence in respect to those five or six names, among which Hunter's name occurred. I certainly think we ought to have had a summary of the evidence, but then if I had applied for such I should have been told I was wasting the time of the Council, as I have been told before. I regard my position as one of extreme difficulty, though not so bad as it was. I think my election at first was rather resented by some of the old members of the Council because it occurred more than once that when *I* had a motion down on the paper and wanted to say something someone popped up and moved the previous question which unfortunately was invariably carried. That, however, does not occur now. There has been much change in the *personnel* of the Council, something like half the Council has changed in the five years. In regard to everything I bring forward now I must say that I am always treated with respect and that facilitates one's position at the Council. One feels more and more at home. As I get to understand the old members better I think at the same time they also get to know George Brown better, and there is more kindly feeling between us in consequence. I shall not say anything in regard to any other candidate who may come forward except *that I feel in justice bound to say that* my colleague Mr. Horsley and myself have worked very harmoniously and happily together during the time we have been on the Council. I am glad to say this because I opposed Mr. Horsley's candidature and supported that of Sir Walter Foster. I thought Sir Walter Foster might have been more useful than Mr. Horsley to general practitioners because of his influence in the House of Commons. We want more representation in the House of Commons and I thought Sir Walter Foster would [illegible]

[illegible] if *Mr. George Brown believed* [illegible] could be restricted by legislation [illegible] a medical man compulsory in cases of confinement, also what policy did he support in connexion with such legislation as was threatened?

Dr. BROWN said he would oppose the present Bill *in toto*. He was in favour of a Bill for the better training of nurses by public bodies [illegible]

[illegible] said that Mr. Brown spoke of a [illegible] was unintelligible. It would [illegible] ered the question whether he believed that it was reasonable or possible to expect the legislature *to pass any measure requiring every obstetric case to be attended by a* medical practitioner. It was no use medical men crying for the moon, something should be asked for which was likely to be granted.

Mr. BROWN said he did not quite understand the question in that direct way.

The CHAIRMAN, at the request of the meeting, then read out Dr. *Ritchie's question to Mr. Brown* who replied that he was sure the legislature would do nothing of the kind. From conversation with Members in both Houses he was certain they would never make that restriction. They could not force a man into a woman's lying-in room and it would be unreasonable to expect it.

DR. GLOVER'S ADDRESS.

[illegible] influence of your representatives. A very serious blow was inflicted on Direct Representation after the last election when one of the gentlemen elected, after clamouring for a seat, left the Council without ever waiting to discuss the main question he was supposed to understand and for the solution of which he was chosen. I have enjoyed your confidence for 15 years—that is, for three separate quinquennial periods—and I am asking you once more to re-elect me. Nobody knows better than I do my many defects and shortcomings, but I have come to the conclusion, in spite of these, that I shall consult the interest of the cause of Direct Representation by sticking to my guns and by seeking re-election. Few members of the Council have seen more of its working; few have had a larger experience of its principal committees, few know better what the Council can do and what *it cannot do than myself. I do not boast* of this. It is simply the length of my experience in the Council as your representative and my knowledge of its members, their attitude of confidence and kindness towards me over this period, that make it so. The Council is not perfect. It is too large. It wants reconstruction and it wants larger powers. But in my opinion it has great powers for good even in its present form, and *I see no immediate chance of it* being materially altered. It has done very much already, as Mr. Brown has admitted, and may do much more both for the public and the profession—for medical education, and for the purity and dignity of the medical profession, which are of enormous consequence to the public. And I believe sincerely that for those ends the presence on the [illegible]

I will [illegible] differ from me on this matter will allow that I have never shirked the question and that I have consistently held that some regulation of midwives practice is urgently required and can scarcely be had without legislation. My support will only be given to a Midwives Bill on two or three very strict and well-defined conditions. First that the practice of uncertified midwives be stopped and penalised, and secondly that the midwife shall be required on the occurrence of any irregularity or abnormality of mother or child to apply to a registered medical practitioner, thus placing her in a distinct, non-medical subordinate position. I have a third condition to [illegible] though I have not been able here as [illegible] Medical Council to agree with me—viz., [illegible] of each district shall be required to [illegible] to the midwife a reasonable fee (not less than a guinea). I have never yet heard any sure arguments [illegible] believe that I have any personal object in the views I hold on this question—I have two objects in supporting a Midwives Bill which I will shortly state. I feel not [illegible] The first is, I wish to abolish the existing untrained [illegible] midwife [illegible] Gamp [illegible] dangerous and deadly [illegible] women who are entitled to the greatest consideration. The second object I have is to abolish the [illegible] of the Obstetrical Society of London in giving certificates to midwives. Here I must be quite explicit. I could be no party to blaming the society for its efforts to raise the [illegible]

[illegible] London, and we have only one punishment and it a capital one—that we should remove their names from the Medical Register. Does any gentleman think that the most advanced medical reformer—Mr. Brown himself, say—would venture to rise seriously and make a definite proposition to that effect in the General Medical Council? To do Mr. Brown justice I must say he has had the chance of doing this any time in the last five years and he has not done it. Gentlemen, what has the Government, the Privy Council, done with one of the chief ornaments of the Obstetrical Society of London? It has made him a Crown Member of the General Medical Council. The only way, and the proper way, to get rid of the irregular and unauthorised action of the Obstetrical Society of London is to create a board, acting under law, to do what it is doing and for which it has in time past had the approval of the public and the tacit approval of the General Medical Council. These are my principal objects in supporting with strict conditions a Midwives Bill. And I would say in dismissing this subject that I have another reason. I feel convinced that such legislation will come to pass and that it will be done independently of the medical profession if it loses the chance of shaping it and controlling and regulating the practice of midwives. Gentlemen, in this matter, as in some others, Mr. Brown poses as the saviour of the medical profession. He has a medical paper all to himself which in the interval of elections undergoes a sort of hibernation, and just before the great event comes to life again and demonstrates to its readers that I am the great sinner—the Jonah—and he is the man to elect to represent the profession. Now I do not believe that the majority of the profession differ from me in thinking that something must be done to get rid of the untrained, dirty, ignorant, often intemperate midwife. What has happened? In the last five years Mr. Brown has never once that I remember in all the midwifery discussions moved the Council to declare that it disapproves of all such attempts at legislation. But he leads his followers to think that he is going to do so and that some great change is going to occur. Gentlemen, let me tell you such a change cannot occur without the Council stultifying itself. I shall tell you what would happen. Mr. Brown would not get a seconder, as happened on a recent occasion to which I shall have to allude further on. I prefer more practical courses and to help the profession to regulate legislation which it cannot and, in my opinion, ought not altogether to prevent.

Gentlemen, the midwives question is only one of a score or a hundred questions that have to be considered by the General Medical Council. I regard the Midwives Bill question as practically disposed of by the General Medical Council. It devoted a special session to it. It has spent thousands of pounds and whole weeks over its principles and it cannot well reopen the question. But there are many other questions to be dealt with by the General Medical Council. Let me remind you of a few of these. The Council is *par excellence* a Council of Medical Education, which must have for its basis a sound preliminary education. I tried to do my duty as your representative on this question. I may be excused for saying that in the very first session after my election to the Council I drew attention to the want o[illegible] clinical and therapeutical subjects and of exami[illegible] The defect was admitted. I was put on the Ed[illegible] resolution I proposed, a resolution on the subject, has been fruitful of good.

The Council has to consider the means of securing the maintenance of a high professional standard of conduct and of work with adaptation to practice among the working classes [illegible] and has suggested the formation of a [illegible] friendly societies on the one hand and [illegible] on the other. The principle of a Conciliation Board has been approved by a committee of the Council of the British Medical Association and there is reason to hope much [illegible] it in the improvement of the position and pow[illegible] ssion in relation to the great friendly societies. [illegible] General Medical Council entitled to great cred[illegible] matter.

It has to discourage degrading and unprofessional modes of promoting practice—especially advertising and touting. I had the pleasure of proposing a resolution meant to discourage these practices. It has been very effective where the evidence of such practices and of the doctor's knowledge of them has been sufficient. One or two large insurance companies with medical aid business have given up the business, and several medical officers have resigned their position under this clause. Mr. Brown tried to counsel the Council to do something more drastic and did not get a seconder.

The Council has been much concerned with the proofs of the large numbers [illegible] who have no medical [illegible] ad the honour of [illegible] loard with Sir Wi[illegible] Duckworth as a deputation on this subject. We had a most sympathetic hearing and have reason to hope that legislation will result that will brace our registration system up and will regard uncertified deaths in a Christian community as a scandal to be inquired into and prevented.

The Council is a complex organism and has much to do in coördinating and harmonising the action of the various medical authorities. There has lately been exhibited an unseemly and injurious friction between the Royal Colleges of England and the General Medical Council. The best friends of medical education must wish to see the end of this discord which threatens to throw back education. I have tried and shall continue to try to urge a *modus vivendi*. The Colleges and the Council can both help each other, while not encroaching on each other's province. At present the question is raised at each Council meeting and threatens to waste much of the Council's money.

My last remark leads me to say a word about the finances of the Council. The money of the Council is the money of the profession and our sittings have lately been so prolonged that our expenditure has exceeded our income. Some gentlemen have advised an annual fee to be paid instead of a single fee for registration. I am much in favour of a single and final payment as at present instead of what would be an annual tax and I believe that with some reforms in the conduct of our discussions the ordinary income of the Council will suffice to meet its expenditure. These, gentlemen, are a few of the subjects that engage, and must engage, our attention, to say nothing of those most painful cases of misconduct which call for the exercise of the disciplinary powers of the Council or of the need for more disciplinary power both for it and the individual medical authorities which we all recognise. To hear some fluent critics you would think that the General Medical Council does nothing and goes on very slowly. Gentlemen, I do not think so. I think that the changes which are taking places in the profession—in its curriculum, in its education, in the public estimate of it, and in the State estimate of it—are enormous and in some aspects serious. I believe if the General Medical Council proceeds in its steady improvement of education and in its steady demand for the maintenance of professional conduct even in the poorest sections of practice it will command more and more the respect of the public, of the medical authorities, and of the registered practitioners of the country who at an election time are called to send men to represent them. Remember that as regards the election it is not the General Medical Council that is on its trial so much as Direct Representation itself. I can imagine nothing more worthy of representation at the Council than the views generated and impressed upon us by the ordinary and varied life of daily and nightly practice and if such experience is at the service of Direct Representation I have good hopes for its extension.

MR. HORSLEY'S ADDRESS.

MR. VICTOR HORSLEY said: I have much pleasure in attending this meeting because I am hopeful that it will be the precursor of many similar meetings and that it will be an annual fixture at the annual meetings of the British Medical Association. With regard to my views on the midwifery question they are exactly what I circularised in my address to the profession when I was a candidate for the General Medical Council four years ago. I still think that registration of existing and prospective midwives is necessary and whether they are called midwives or midwifery nurses some form of registration is necessary and will be insisted on by the Legislature. It is also in accord with my principles that what both Dr. Glover has suggested and what has been more fully suggested in the *Medical Guild Quarterly* should be carried out. I think it is a perfectly feasible way of dealing with the subject. That is my personal opinion. Our duty as members of the General Medical Council is to see as far as we can that the Government will not lend their support to any measure which does not embrace the 10 points that are given in detail in the minutes of the General Medical Council, the 10 points which the Council consider are essential in this subject. This brings me to the action of the Government not only towards us in regard to the midwifery question but also in regard to other questions. You must know that the General Medical Council is practically a sub-department of the Central Government; its head is the Privy Council; the head of the Privy Council is the Duke of Devonshire. If you will study the minutes of the Council in respect to previous questions you will find that the President of the General Medical Council is in communication with the Privy Council in various ways. You will find the letters that passed between the two bodies, and yet in spite of this repeated communication between these bodies extending over all these years it is a fact that the Privy Council has during the last 10 months treated the General Medical Council with superlative contempt. You will find all the facts in our minutes. The Privy Council is at the present moment utterly disregarding the General Medical Council and its 10 points which include the safeguards necessary in midwifery legislation. And why? Because of what is called the respect of authority and because of what is known as negotiations. We cannot parley with the enemy at the gate; it is ridiculous for us to consider that as a sub-department of the Government we can through our President or through anyone else influence the Privy Council privately. We cannot do it. The only way to do it is through the voice of the profession. Now, thanks to the work which has been effected at this meeting of the British Medical Association, I believe that we shall get this power, but until then let me warn this meeting that at the present time the General Medical Council is unable to do what it wishes to do in this matter. I personally am responsible for endeavouring to send up a protest to the Privy Council against its behaviour towards us as its sub-department. Dr. MacAlister, however, opposed me and succeeded very easily in persuading the Council, so that no protest was sent. All that I can do is to try to endeavour to support the authority of the General Medical Council and I should like to point out that this action of the Privy Council during the last 10 months is no isolated instance. For example, the Executive Committee of the General Medical Council took upon itself to conduct negotiations with the Privy Council on the subject of reciprocity of practice in Italy. Now whatever views we hold, and I hold there is no true reciprocity as arranged, at least we are entitled to consideration; but no, the Privy Council passed an order entirely disregarding our views as a Council. So the Privy Council for a second time in 10 months has treated the General Medical Council with contempt. As regards the work of the Council in education this matter of the Colleges is really a very grave question. It is a step taken by the Royal Colleges which is subversive of the present five years' curriculum and of the best interests of the medical profession and it will ruin students' registration. The representative of the Royal College of Physicians, which body is now tottering to financial ruin, did not hesitate to state in the Council, and his speech unfortunately made a most favourable impression on the Council as a whole—this representative actually said that he was willing to ruin students' registration simply to carry out the wishes of his College. I warn you not to enter into any compromise on this matter. If you support this view you will do what in the opinion of all teachers of medicine in this country will lead to an irreparable injury to the medical profession. As regards preliminary professional education headway is being made in this matter by the Council itself quite irrespectively of this step taken by the Royal Colleges. This question of education is coincident with the question of the one-portal system. Until this plan is endorsed, as I hope it will be by the real voice of the profession at Manchester, we shall not get any further with the General Medical Council, because the compromise with the two Royal Colleges is nothing more than the general feeling of the corporations represented in the Council. The Royal Colleges are going to get a greater number of students to enter for their examinations and the Colleges will receive the fees. The other licensing bodies naturally think, Why should not we do the same? By the constitution of the General Medical Council it is unable to receive a scheme for the one-portal system for the Council is co[illegible]*ng bodies and is thus* really unfit to [illegible] now to the necessity of having a [illegible] may ask me, How do we stand in t[illegible] regard to this matter and what chance is there of success? I am rather surprised at the result of three and a half to four years' work on the Council When I [illegible] *taken up with obtaining ordinary con-* [illegible] that for about a year I was unable to [illegible] ever, swept away the men who were [illegible] It has caused hard words and some [illegible] have gone and in their place we have a younger set of men, amongst them Deans of Medical Schools who are keenly *interested in general medical education* These men are men to whom you can appeal with reason and the outlook for the Medical Act Amendment Bill is better. But the body of the General Medical Council consider that such a Bill should come from the British Medical Association, and I am willing to accept that position Let us meet them half way, let the *British Medical Association go on with the work of* [illegible]tee, and let us bring to the General [illegible] ask for In such a Bill I think I [illegible] qualified practice should take first [illegible] of that of course the House of [illegible] require, that the constitution of [illegible] *that it should be deprived of its* corporate body—that is to say, its commercial character—so that it shall be made a representative council, and if the House of Commons demanded it there should be an addition of one or two more Crown members. There must be a bargain and we must give something in return if we are to get anything out of the House of Commons I have left my next point to the last because I believe it is a lever by means of which we shall reform the General Medical Council I come to the question of money, which, as usual, is at the bottom of most things We have now got to the bottom of the pocket of the Council and the Council is in a bad way and may find it necessary to go to the House of Commons and ask for some change in legislation which it can put into operation *in order that it may live* So that I am hopeful in this matter of finance You will remember [illegible] must say, by Mr Bryant. However, after a long series of wrangles we at last succeeded in getting a report from an expert in finance, Mr Frere. Mr Frere's report confirmed in every minute detail not only the facts which I had brought forward two or three years before but Mr Frere proposed as reforms everything that we had been asking for. Now that is a most remarkable thing, for I had no communication with Mr. Frere and I never had told him of the discussions that had taken place in the reform [illegible] reforms we had [illegible]h I must deal [illegible] us his opinion [illegible] be really opera[illegible]n To return, [illegible]e, which I per[illegible]erly discussed, we look to the [illegible] threshed out so [illegible] in the matter [illegible] stewardship in [illegible] the reports to the profession I have from time to time issued, and I shall continue that action if you re-elect me I only wish to conclude by expressing my intense gratification that we are at last likely to be in a position through the British Medical Association to be able to instruct our representatives as to what they ought to do

[illegible] When I was a candidate for [illegible]er occasion I polled over 4000 [illegible] now and having been asked by [illegible]ou I come forward as a candi[illegible] of the midwives the trend of [illegible]*ms to be*, and I have talked [illegible] in favour of some form of registration We ought to try to guide legislation so that it shall [illegible] Campbell that that was carried out at Saddleworth, the payment for *the services rendered being regarded as a loan* In Jamaica it was also done and there advances were made to pay for the doctor and for the [illegible] was [illegible] but at any rate the mortality is very considerable, and it behoves us therefore, to take more care of our population producing people, to take more care of the mothers of the country and not to allow them to die in this way and to take more care of the children He suggested that the British Medical Association should introduce a Bill into Parliament on the lines indicated in the *Medical Guild Quarterly* and there should be a regular system of nurses, that they should have from two to three years' training before they were allowed to have anything to do with nursing as a sufficient training was necessary so as thoroughly to drill the nurses in their work, because if taught only for a limited time the nurses *lapse into careless ways* It was more important for the public at large to be well nursed than to be well doctored. The whole body of the profession as represented by the Bri[illegible] have more weight with the professio[illegible] Direct Representatives and of cutting up the country into smaller electoral districts The General Medical Council would thus be able to promote legislation favourable to the profession and to the country at large In the House of Commons you must *insist that it is for the benefit* of the country at large We must improve matters in that way For instance, as regards quacks who are allowed to practise as aurists and oculists they should be [illegible] registration of deaths, because of the enormous number of uncertified deaths We have examples of this in cases in which chemists attend *people and simply write a note to the registrar informing him of the* death. Stillbirths also should be registered. I do not suppose I have touched on all the points, but I think I have touched on the main points I cannot claim personal experience like the present Representatives, but if elected I shall carry out the duties as far as I can

Dr. S WOODCOCK, J P *(Manchester) said: I do not know that* I am a candidate My position and attitude in regard to this question is this In the first place we are entitled to a representative from the north of England, and I do not think that all our representatives should be in London Other places should have some share in representation When approached I said that if it was *apparent that the bulk of the profession in the north of England* desired me as a candidate I was at their service I have no personal [illegible] when I approached members of the House of Commons and the House of Lords I was met with a simple reply: "What do you propose instead, because their must be some legislation, and things can't [illegible] disposed of the men who were giving the certificates But all this was only done with the idea of it being submitted to Parliament if the other proposed Bill came before the House Our Bill was to be put in only in order that it should not be said that we had nothing to suggest I consider that to insist on a medical man being called in in every case of confinement is impracticable and it is not possible for the Government to consent to that This present Government appears to be in for a long tenure of office and there is a weak Opposition You may judge what the attitude of the Government is on this question when I tell you that with all our efforts we could never get at the President of the Privy Council We tried again and again to get him to receive a deputation but we were never allowed to see him On the other hand, the promoters of the Midwives Bill have had no difficulty and they were encouraged by him to go on No difficulty was placed in their way and when a vacancy occurred on the General Medical Council of a [illegible] *to the man through* [illegible] and the worst Registra[illegible] Sir John Williams was [illegible] the Government has put Sir John Williams on the General Medical Council Is the Government going to agree to a Bill like the Medical Guild Bill? I do not *disapprove of it* but I want something to be done in my lifetime and I want something done now. Is it desirable that these men should be allowed to go on giving these midwifery certificates? Is it desirable that you should have people unregistered and consequently uncontrolled or is it not better that something should be done which should be a *safeguard* to the public? If there was any *unanimity of the profession* and if there was any encouragement from the public you might hope to insist on a medical man being called in to each confinement But it is absurd to believe in any such thing which is so far from being practical In our Bill we laid down distinct[illegible] and there were certain stated circumstances under which a woman should be compelled to call in a medical man, but for every confinement it is not practicable If I go to the General Medical Council I must go and be able to feel that I am speaking what I really believe I would not propose resolutions which could not be passed and would be ineffectual if they were I am generally in approval of the attitude and policy of Mr Horsley and I agree with him on this midwives question I am not supporting the measure in favour of the registration of midwives Our Bill was altered in its title by the Council of the Association—the name was not altered by the Committee I have also taken some part in attempting to draft a Medical Act Amendment Bill and there I have sufficiently indicated my opinion in regard to the [illegible] Then it will be carried by the [illegible] I think that we should aim at [illegible] is not creditable that we should have [illegible] *into the profession.* If the Council is paralysed for funds we should go to Parliament and get [illegible] to ha[illegible] fee. Lawyers do it and so do other men who [illegible] r than we do. I know something of the work [illegible] have had some experience in public life and if the medical profession should think that I have the ability and the tact to represent them sufficiently well I am prepared to place myself at their service.

Dr. RITCHIE said after the speeches they had listened to the midwives question must be excluded from that election; to introduce it would be throwing dust in the eyes of the electors.

Mr. G. H. BROADBENT (Manchester) said that he thought just the opposite. It was most essential to prevent the establishment of an inferior order of practitioners.

The CHAIRMAN then repeated the following question to the candidates: Did they believe it probable that the practice of midwives will be restricted by legislation so as to make the attendance of a medical man compulsory in cases of confinement? which was replied to in the negative.

In reply to Dr. A. Cox (Gateshead) Dr. GLOVER said that he voted for the present form of certificate issued by the London Obstetrical Society and it would be remembered that it used to be a diploma. He would continue his present attitude until some legal body was provided to look after that business.

Dr. MAJOR GREENWOOD said that the General Medical Council had made the Obstetrical Society alter the diploma issued to midwives into a certificate. What was it that led those who held certificates to go on using the term "L.O.S."?—that could only imply licentiate. That was the most important point and that was omitted by the Council. It was a deception and the General Medical Council should take notice of it because licentiate was a medical title.

Mr. WOLSTENHOLME asked if Dr. Glover had afforded Mr. Horsley any assistance when Sir William Turner, the chairman of the General Medical Council, had refused to allow Mr. Horsley access to the documents of the Council.

Dr. GLOVER said that he did not remember the facts as to the first resolution of the Council about the documents. The ultimate resolution, however, by which the documents were accessible was moved by him. He explained that he had no other object than to secure first the care of the documents, and secondly the right and convenience of members in the use of them. The present resolution of the Council was drawn up by him in place of the first one which, though he supported it. was not quite satisfactory.

Mr. WOLSTENHOLME asked with regard to the Royal Colleges and their scheme, it appeared to reduce the medical curriculum to four years. As Dr. Glover had spoken of a *modus vivendi* would he say if that was to prevent the five years' course being shortened to four years?

Dr. GLOVER replied that he had no intention of disturbing the five years' course and there was not one instance in which the Colleges had accepted less than a five years' curriculum. They included in that curriculum one year passed at a preliminary educational institution approved by them.

Mr. WOLSTENHOLME asked if Dr. Glover agreed to that.

Dr. GLOVER answered that he agreed with that till the Council had power to interfere with the legal rights of the Colleges, otherwise they would be landed in an appeal to the Privy Council which they would lose.

Mr. WOLSTENHOLME then turned to Mr. Horsley and asked him whether he had found any difficulty in his attempt to inspect the documents of the Council, whether he had been thwarted in that application, and whether Dr. Glover had given him proper support on that occasion. He also asked whether Mr. Horsley was in favour of the *modus vivendi* with the Royal Colleges permitting the five years' course to be curtailed to four years.

Mr. HORSLEY said: Dr. Glover has told us that his memory does not serve him in regard to the first session when the question of the documents came up. I have to say that mine does; the facts are burnt into my memory. The Chairman of the Council locked up the documents which were public property and which I had a right to inspect. When I made my protest I was opposed by Dr. Glover so strongly that actually I could not obtain a fair hearing. I am speaking of the first session which Dr. Glover does not remember. I was so strongly opposed that I could not obtain a fair hearing and during the whole of that week's work I was looked upon as a kind of outcast for having endeavoured to disorderly interrupt the Chairman. That was the state of affairs, *but I carried* my point at the next session and what Dr. Glover says is true. It was on his motion that the documents are now inspected. It is a ridiculous thing that there should have been any reason for such a proposal at all, but it is what we work under at the present time. With regard to the *modus vivendi* with the Colleges I want to say that the Colleges have legal rights under their charters and the Council has legal rights under the Medical Acts, but owing to the carelessness of the [illegible] 386 was drawn up purporting to be an Act [illegible] ll the corporate bodies, a clause was left [illegible] the Council was the head of all these bodies. That clause having been omitted, if you were to bring the matter before the courts [illegible] would have to say both parties were in the r[illegible] sition and I intend to resist any attempt [illegible] profession in going to law in this matter. [illegible] *vivendi*. If the Council chooses to succu[illegible] ssible, and unless the Direct Representativ[illegible] the profession behind them that the Cou[illegible] er position a very grave injury will be done to the medical profession.

Mr. BROADBENT then asked if the candidates opposed legislation for midwives, making them independent practitioners, and was answered affirmatively.

Mr. BROADBENT again rose and wanted to know if the candidates considered that it was for the good of poor women that every case of midwifery should be more or less under the direct and personal supervision of a medical man even if details were conducted by a trained and registered nurse, and received affirmative replies.

Dr. C. H. MILBURN asked if the candidates would furnish reports to the profession like those supplied by Mr. Horsley to which he was answered in the affirmative.

Dr. S. CRAWSHAW wanted to know if any legislation in midwifery was to be restricted to a particular class, and was replied to by the candidates to the effect that the legislation was for the poor, but that it was impossible to prevent the public using their own discretion in the matter.

Dr. MAJOR GREENWOOD pointed out that in the event of legislation for midwives particular attention should be directed to securing local registration by the sanitary authorities.

Mr. WHITAKER, in moving a vote of thanks to the candidates for their speeches, especially welcomed the candidates from the provinces. They had three representatives who were in London and it was for the profession to show that they preferred two of the candidates to be from the provinces. It was very satisfactory to note how competent Mr. Jackson and Dr. Woodcock were to represent the profession on the General Medical Council. If they elected one representative for London with Mr. Jackson from Plymouth and Dr. Woodcock from the north it would be most satisfactory. It was very satisfactory to be certain that Mr. Jackson and Dr. Woodcock, if elected, would coöperate with their London colleague.

Dr. MILBURN, in seconding the vote of thanks, pointed out the advantages of electing two out of the three candidates from the provinces.

Mr. WOLSTENHOLME regretted that Mr. Whitaker had suggested to the profession whom they should elect.

Mr. WHITAKER replied that he did not suggest anything. He said it would be gratifying if one candidate was elected from London together with Mr. Jackson and Dr. Woodcock from the provinces.

Mr. WOLSTENHOLME said the profession would not stand Mr. Whitaker's suggestion for one moment. Medical men were quite able to criticise and judge for themselves.

A vote of thanks to the Chairman terminated the proceedings.

THE PATHOLOGICAL INSTITUTE OF THE LONDON HOSPITAL.

THIS compact and excellently arranged building serves the threefold purpose of hospital mortuary, post-mortem room, and pathological laboratory and is so constructed that each part can be entirely shut off from the other two when necessary. It stands in a large quadrangle and is entirely separated from the hospital buildings by an air-shaft. It consists of two storey, the lower devoted entirely to the mortuary and post-mortem room arrangements, the upper to the pathological laboratories. On the ground floor there is a long corridor or main passage reaching from end to end of the building, to which the bodies are brought from the hospital on enamelled metal slabs slightly curved and fitted underneath with sleigh-runners to facilitate movement of them from the trollies on to the storing-frame. They are taken to the mortuary store, which is an offshoot of the main corridor and contains a very convenient contrivance for storage of the bodies previously to section. It consists of a large metal frame made in segments and easily taken to pieces, either in part or entirely, for purposes of cleaning. The metal slabs are arranged so as to slide easily over rollers placed transversely in each segment of the frame. There is an admirable arrangement by which any exudation can be drained from these slabs. To one side of this store is a very effective cold chamber of simplified construction, worked by the carbon-dioxide process and capable of storing 12 bodies; to the other side is a tank-chamber for storage of material. From the mortuary store the bodies can be taken into the post-mortem room for section. This is a large room, lofty, well ventilated, and with excellent lighting both from the top and sides. It contains two white enamelled porcelain tables capable of rotation and discharging into an open circular gutter, and there is also in another part of the room a tank for sections under water or other fluid. There are cupboards for appliances, reagents, and other apparatus. Leading from the main room is a smaller one of similar character with one table for special necropsies.

The students' entrance to the post-mortem room is in the front of the building and is quite separate from that from the main corridor at the back through which the bodies are brought and into which they are again taken after section and conveyed to the main mortuary. This is a large room at the end of the corridor, containing a frame in all respects similar to that in the mortuary store room, on which the bodies remain till placed in the coffins. when they are conveyed into a simple but tastefully decorated mortuary chapel, to which the patients' friends are admitted through a small lobby with an entirely separate entrance in the front of the building. Noteworthy features of this department of the building are the excellent arrangement of the various rooms about the main corridor, the frames and slabs for storage purposes, and the conveniences for the friends to view the bodies.

The pathological department is on the first floor and has an entirely separate entrance in the front of the building, though it can be entered from the post-mortem room direct by those with a pass key. It consists of a large laboratory, a bacteriological room, private rooms for the director and two assistants, a chemical laboratory, and a research laboratory, with preparation and mechanics' rooms. The main laboratory is a large and lofty room with excellent light in all parts, with benches, lockers and stain cupboards, for 12 workers [illegible] each with separate [illegible] removeable to [illegible] the stain cupboard [illegible] the stains to be kept away from the light. There are separate microscope lockers at one end of the room. Two medium sized sinks are placed in the middle of the room with racks over them for reagents, and are fitted for the dissection and preparation of specimens. There [illegible] round all four sides of the laborat[illegible] for the storage and preparation o[illegible] vestigation. The bacteriological annexe to this room is for the investigation of material obtained in the post mortem room. The director's and the assistants' private rooms are fitted for research work, as also is the research laboratory which can accommodate two or three workers engaged on special work. The chemical laboratory is arranged with benches and racks for five men, with special slate slabs for *Kjeldahl determinations and stone slabs for combustions.*

The whole building throughout is lined with glazed brick, with terazzo flooring, and can therefore be easily cleaned. The ventilation is good and is effected by a number of large lamp ventilators supplemented by electric fans in certain of the rooms. It is evident that very great care and consideration have been given to its construction and the arrangements are admirable in every way. It forms a very striking and noteworthy addition to the resources of the London Hospital and will doubtless attract many workers to avail themselves of the almost unrivalled opportunities afforded for pathological study and research.

VITAL STATISTICS

HEALTH OF ENGLISH TOWNS.

IN 33 of the largest English towns 6096 births and 4658 deaths were registered during the week ending July 27th. The annual rate of mortality in these towns, which had been 15·1, 15·6 and 17·9 per 1000 in the three preceding weeks, further rose during the week to 21·2. In London the death rate was 18·2 per 1000, while it averaged 23·2 in the 32 provincial towns. The lowest death rates in these towns were 9·7 in Croydon, 10·8 in Derby, 12·3 in Cardiff, and 12·4 in Halifax; the highest rates were 30·0 in Birkenhead, 30·2 in Portsmouth, 31·7 in Sheffield, and 34·3 in Liverpool. The 4658 deaths in these towns included 1508 which were referred to the principal zymotic diseases, against 431, 567, and 897 in the three preceding weeks; of these 1191 resulted from diarrhoeal diseases, 114 from measles, 68 from diphtheria, 64 from whooping cough, 45 from scarlet fever, and 26 from "fever" (principally enteric). No death from any of these diseases occurred in Halifax; in the other towns they caused the lowest death rates in Plymouth, Derby, and Oldham, and the highest rates in West Ham, Portsmouth, Birkenhead, Liverpool, Burnley, Leeds, and Sheffield. The greatest mortality from measles occurred in West Ham, Birmingham, Birkenhead, and Gateshead; from whooping cough in Brighton, Swansea, and Sunderland; and from diarrhoeal diseases in Portsmouth, Birkenhead, Liverpool, Burnley, Leeds, and Sheffield. The mortality from scarlet fever and from "fever" showed no marked excess in any of the large towns. The 68 deaths from diphtheria included 28 in London, five in Sheffield, and four in Salford. No fatal case of small-pox was registered during the week in any of the 33 towns. There were 11 small-pox patients under treatment in the Metropolitan Asylums hospitals on Saturday, July 27th, against five, six, 12, and 14 at the end of the four preceding weeks; two new cases were admitted during the week, against two, six, and five in the three preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the week was 2974, against 2918 and 2907 on the two preceding Saturdays; 374 new cases were admitted during the week, against 363, 324, and 371 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 165, 133, and 135 in the three preceding weeks, declined again during the week to 133, and were 43 below the average. The causes of 51, or 1·1 per cent., of the deaths in the 33 towns were not certified, either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Bristol, Nottingham, Salford, and in 13 other smaller towns; the largest proportions of uncertified deaths were registered in Swansea, Birmingham, Liverpool, Halifax, Sunderland, and Newcastle.

In 33 of the largest English towns 7180 births and 4926 deaths were registered during the week ending August 3rd. The annual rate of mortality in these towns, which had increased from 14·8 to 21·2 per 1000 in the five preceding weeks, further rose last week to 22·4 per 1000. In London the death rate was 20·0 per 1000, while it averaged 24·0 in the 32 large provincial towns. The lowest death-rates in these towns were 9·7 in Croydon, 11·4 in Halifax, 11·6 in Wolverhampton, and 13·1 in Bristol; the highest rates were 30·2 in Liverpool, 31·0 in West Ham, 31·7 in Newcastle, and 33·0 in Gateshead. The 4926 deaths in these towns included 1755 which were referred to the principal zymotic diseases, against 567, 897, and 1508 in the three preceding weeks; of these, 1436 resulted from diarrhoeal diseases, 120 from measles, 69 from diphtheria, 56 from whooping cough, 43 from scarlet fever, 30 from "fever" (principally enteric), and one from small-pox. The lowest death rate last week from these diseases were recorded in Croydon, Plymouth, Bristol, Wolverhampton, and Halifax; and the highest rates in West Ham, Liverpool, Manchester, Salford, and Preston. The greatest mortality from measles occurred in West Ham, Birmingham, Salford, and Sheffield; from scarlet fever in Blackburn and in Preston; and from diarrhoeal diseases in West Ham, Portsmouth, Liverpool, Manchester, Preston, and Sheffield. The mortality from whooping cough and from "fever" showed no marked excess in any of the large towns. The 69 deaths from diphtheria included 28 in London, six in Leeds, five in Leicester, and five in Sheffield. One fatal case of small-pox was registered last week in London, but not one in any other of the 33 large towns. 13 small-pox patients were under treatment in the Metropolitan Asylums hospitals on Saturday, August 3rd, against 12, 14, and 11 on the three preceding Saturdays; four new cases were admitted during the week, against six, five, and two in the three preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the week was 3091, against 2907 and 2974 at the end of the two preceding weeks; 391 new cases were admitted during the week, against 324, 371, and 374 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 135 and 134 in the two preceding weeks, further declined to 125 last week, and were 43 below the average. The causes of 43, or 0·9 per cent., of the deaths in the 33 towns last week were not certified, either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Nottingham, Bradford, Leeds, Newcastle, and in 11 other smaller towns; the largest proportion of uncertified deaths were registered in Liverpool, Preston, Sunderland, and Gateshead.

in Greenock. The deaths from measles, which had been 25, 24, and 22 in the three preceding weeks, further declined to 16 during the week under notice and included 11 in Glasgow and five in Dundee. The fatal cases of whooping-cough, which had been 25 and 22 in the two preceding weeks, further decreased to nine, of which five were registered in Glasgow and three in Edinburgh. The deaths from scarlet fever, which had been four and seven in the two preceding weeks, declined again to six, and included four in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 95, 79, and 75 in the three preceding weeks, further decreased during the week under notice to 56, and were 11 below the number in the corresponding period of last year. The causes of 24, or more than 4 per cent., of the deaths in these eight towns were not certified.

The annual rate of mortality in the eight Scotch towns, which had been 18·4 and 17·8 per 1000 in the two preceding weeks, rose again to 19·8 per 1000 during the week ending August 3rd, but was 2·6 per 1000 less than the mean-rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 14·4 in Paisley and 15·8 in Aberdeen to 22·1 in Greenock and 22·9 in Dundee. The 630 deaths in these towns included 128 which were referred to diarrhœa, 28 to whooping-cough, 13 to measles, two to scarlet fever, two to "fever," and one to diphtheria. In all, 174 deaths resulted from these principal zymotic diseases last week, against 89 and 134 in the two preceding weeks. These 174 deaths were equal to an annual rate of 5·5 per 1000, which was 2·5 per 1000 below the zymotic death-rate during the same period in the 33 large English towns. The fatal cases of diarrhœa, which had been 29, 45, and 99 in the three preceding weeks, further rose last week to 128, of which 73 occurred in Glasgow, 15 in Dundee, 12 in Edinburgh, nine in Leith, eight in Greenock, four in Aberdeen, four in Perth, and three in Paisley. The deaths from whooping-cough, which had been 25 and nine in the two preceding weeks, increased again to 28 last week, and included 19 in Glasgow, five in Edinburgh, and three in Dundee. The fatal cases of measles, which had been 24 and 16 in the two preceding weeks, further declined last week to 13, of which seven were registered in Glasgow, three in Dundee, and two in Edinburgh. The deaths referred to diseases of the respiratory organs in these towns, which had been 79 and 56 in the two preceding weeks, rose again last week to 65, but were slightly below the number in the corresponding period of last year. The causes of 34, or more than 5 per cent. of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 20·7, 21·0, and 18·4 per 1000 in the three preceding weeks, rose again to 20·6 per 1000 during the week ending July 27th. During the four weeks ending July 27th the death-rate has averaged 20·2 per 1000, the rates during the same period being 15·8 in London and 17·3 in Edinburgh. The 148 deaths of persons belonging to Dublin registered during the week under notice were 16 in excess of the number in the preceding week, and included 26 which were referred to the principal zymotic diseases, against seven, 10, and 18 in the three preceding weeks; of these 20 resulted from diarrhœa, four from whooping cough, one from diphtheria, and one from cholera. These 26 deaths were equal to an annual rate of 3·6 per 1000, the zymotic death-rate during the same period being 5·0 in London and 2 6 in Edinburgh. The fatal cases of diarrhœa, which had been four and 14 in the two preceding weeks, further increased to 20. The four deaths from whooping-cough slightly exceeded the average number in recent weeks. The 148 deaths in Dublin during the week under notice included 35 of children under one year of age and 38 of persons aged upwards of 60 years; the deaths both of infants and of elderly persons showed a slight excess over the numbers recorded in the preceding week. One inquest case and four deaths from violence were registered during the week; and 54, or more than one-third, of the deaths occurred in public institutions. The causes of six, or more than 4 per cent., of the deaths in Dublin were not certified.

The death-rate in Dublin, which had been 18·4 and 20·6 per 1000 in the two preceding weeks, was again 20·6 during the week ending August 3rd. During the past four weeks the death-rate has averaged 20·2 per 1000, the rates during the same period being 17·2 both in London and in Edinburgh. The 148 deaths of persons belonging to Dublin registered during the week under notice included 32 which were referred to the principal zymotic diseases, against 10, 18, and 26 in the three preceding weeks; of these, 23 resulted from diarrhœa, four from whooping-cough, four from cholera, and one from "fever." These 32 deaths were equal to an annual rate of 4·4 per 1000, the zymotic death-rates during the same period being 6·0 in London and 3·4 in Edinburgh. The fatal cases of diarrhœa, which had been four, 14, and 20 in the three preceding weeks, further rose last week to 23. The deaths from whooping-cough corresponded with the number in the preceding week, while the mortality from cholera showed an increase. The 148 deaths registered in Dublin last week included 43 of children under one year of age and 31 of persons aged upwards of 60 years; the deaths of infants exceeded the number recorded in the preceding week, while those of elderly persons showed a decline. Eight inquest cases and six deaths from violence were registered; and 53, or more than a third, of the deaths occurred in public institutions. The causes of five, or more than 3 per cent., of the deaths in Dublin last week were not certified.

THE SERVICES.

Royal Navy Medical Service.

Surgeon T. D. Halahan to the *Pioneer*.

Royal Army Medical Corps.

Surgeon-Lieutenant-Colonel S. Farrant, West Somerset Imperial Yeomanry, is appointed to the medical charge of troops at Taunton. Lieutenant-Colonel Franklin is posted to the Cambridge Hospital, Aldershot, for duty. Lieutenant Wells is posted to the Royal Artillery hut barracks at Deepcut, Frimley, for duty. Lieutenant-Colonel A. H. Keogh, C.B., is appointed for temporary duty at the War Office. Lieutenant H. A. Davidson takes charge of the Station Hospital on Wilberforce Hill, Sierra Leone, and Lieutenant Hull is in the outlying country near Sierra Leone with a detachment of the West African Regiment,

The undermentioned Lieutenants to be Captains, dated July 27th, 1901:—George Snyder Nickerson, George Bedford Crisp, Robert Strickland Hannay Fuhr, Walter Jagger, George Johnston Stoney Archer, Robert Selby, Sidney Octavius Hall, Alfred Edmond Weld, James Stuart Gallie, Francis Joseph Christopher Heffernan, Arthur Edward Thorp, Cecil Wilmot Mainprise, Henry Herrick, Edward John Dobbin, James Cowan, Austin Romuald O'Flahertie, Henry Beckles Gall Walton, and Edmund Philip Hewitt.

Civil Surgeon Charles Glendenning Thomson to be Lieutenant. Dated August 3rd, 1901.

Imperial Yeomanry.

Derbyshire: Richard Mervyn Wilson to be Surgeon-Lieutenant. Dated May 24th, 1901.

Army Medical Reserve of Officers.

Surgeon-Captain J. V. W. Rutherford to be Surgeon-Major. Dated August 3rd, 1901. Surgeon-Captain James Cameron, 6th Volunteer Battalion the Royal Scots (Lothian Regiment), to be Surgeon-Captain. Dated August 3rd, 1901.

Volunteer Medical Staff Corps.

The London Companies: Surgeon-Lieutenant E. B. Waggett to be Surgeon-Captain. Dated August 3rd, 1901.

The Woolwich Companies: William Henry Payne to be Surgeon-Lieutenant. Dated August 3rd, 1901.

Volunteer Corps.

Artillery: 1st Forfarshire: The undermentioned officer resigns his commission: Surgeon-Lieutenant R. Soutar. Dated August 3rd, 1901. 1st West Riding of Yorkshire (Western Division, Royal Garrison Artillery): Surgeon-Lieutenant A. L. Whitehead to be Surgeon-Captain. *Rifle:* 2nd Volunteer Battalion the Duke of Cornwall's Light Infantry: Surgeon-Captain W. Nettle to be Surgeon-Major. Dated August 3rd, 1901. 1st Dumbartonshire: The undermentioned Surgeon-Lieutenants to be Surgeon-Captains: D. Christie, dated July 17th, 1900; C. F. Spinks, dated

April 3rd, 1901 19th Middlesex (Bloomsbury) Surgeon Captain A. W Wigmore resigns his commission. Dated August 3rd, 1901

Correspondence.

ARE BOVINE (PERLSUCHT) AND HUMAN TUBERCULOSIS IDENTICAL?

To the Editors of THE LANCET

SIRS,—On March 10th 1880 a communication was made by *Professor Virchow to the Berlin Medical Society and* subsequently printed in the *Berliner Klinische Wochenschrift* of April 5th and 12th [illegible] der Hausthiere und deren [illegible] which may be advantage[illegible] The results arrived at after several years' experimentation under Professor Virchow's own direction are given and great stress is laid upon the specific characters which distinguish bovine (Perlsucht) from human tuberculosis The two following paragraphs are specially interesting—bearing in mind that they were written two years before Dr Koch announced his discovery of the tubercle bacillus in the *Berliner Klinische Wochenschrift* of April 10th, 1882.

> The fact that Klebs succeeded in developing pearl nodules by injecting human tuberculous matter in the calf certainly seems to prove that the two products are of the same nature Such a proof would unquestionably be conclusive did we not know that in animals [illegible] tuberculous infection is due [illegible] this micro-organism has not [illegible] not à *priori* deny its existe[illegible] to wait and see whether a [illegible] source both of tubercle and of pearl nodules
>
> In the meantime I think it important we should recognise that Perlsucht (bovine tuberculosis) runs a different course from tuberculosis in the human subject I would point specially to the fact that ulceration *is directly associated with caseous degeneration* The ulcer is produced by softening of the caseous matter (aus dem Käse geht durch Erweichung das Geschwür hervor) If any deposit similar to tubercle does not undergo caseous degeneration there is then no tendency to ulceration This is precisely the condition in bovine tuberculosis In cattle we do not find phthisis ulcerosa de-[illegible] firm tumours which become [illegible] which may finally reach the [illegible]ant differences and in the [illegible] designate pearl nodules as pearl nodules and tubercle as tubercle If we wish to express a dogmatic view of the matter we may say that pearl nodules represent tubercle in cattle but we must always maintain that both the course they take and their structure are different to what we see in the human subject *In any case we must bear in mind that as yet no individual has ever contracted pearl nodules from eating the flesh of animals affected with bovine tuberculosis*—therein lies the theoretical difficulty (Jedenfalls muss man sich erinnern dass noch niemals ein Mensch durch den Genuss perlsüchtigen Fleisches Perlknoten bekommen hat—Das war die theoretische Schwierigkeit)

I am Sirs yours faithfully,

Cambridge August 3rd 1901 P W LATHAM

"THE SALE OF DRUGS BY MEDICAL GRADUATES"

To the Editors of THE LANCET

SIRS,—I am instructed to send you the annexed copy of a resolution recently adopted by the Senatus Academicus of this University and to request that you will kindly give it a place in the next issue of THE LANCET I may mention that a similar resolution has been adopted by the University of Aberdeen

I am Sirs yours faithfully,
I J GRANT,
Secretary of Senatus

University of Edinburgh August 6th 1901

[COPY]

'Whilst it is admitted that the exigencies of practice in certain localities may sometimes render it unavoidable for a medical practitioner to supply to his patients the remedies which he prescribes—the Medical Faculty of this University is of opinion that it is undesirable and detrimental to the position of medical graduates of the University that this custom should be followed under other circumstances; and further it regards the sale of objects other than remedies by its medical graduates as, under all circumstances to be strongly deprecated

THE EDUCATION AND EXAMINATION OF OFFICERS FOR THE ARMY

To the Editors of THE LANCET

SIRS —In the discussion in Parliament upon the subject of army reform one of the most important considerations should be the education and examination of officers

In submitting the following observations I venture to premise that few men in my profession have earned a better right of counsel than myself, since I have served one of the largest and most renowned public schools of England for a *period of 30 years and have thus been enabled to perceive* and to weigh the good and evil features in the system of forming and educating officers

It is not many years ago that the boy who could pass into the army from school was a *rara avis* For most lads had to seek the intervention of that class of teacher called the "crammer," to whom many parents and boys owe a deep debt of gratitude for assistance at a time when little other help was accessible In recent years the public schools have seen the error of their ways and have removed the difficulty by preparing boys for admission direct to Woolwich and Sandhurst with marked success This course has also involved the advantage of preserving the continuity between school life and the army

I am not concerned in discussing the character of the *education* in practice for the purpose required beyond observing that the education of a considerable proportion of young Englishmen is somewhat hampered by the requirements of the military entrance examinations which is shown by the fact that of the large numbers who are specially prepared for this profession about one third only, roughly speaking, are able to obtain commissions, while the remaining two thirds have become specialised to their own detriment The numbers vary year by year according to the requirements of the army, the actual figures for 1897, the year before any war preparations were made being 1300 candidates for 373 commissions If a general school education is a sufficient preparation for the universities and for the learned professions it ought to be adequate for the army without any special preparation prior to entry at Woolwich or Sandhurst If not, then so much the worse for the education Why should such a requirement be necessary in a public school as an army class? If it be why should not the public schools be requested to provide navy, university clerical medical legal and commercial classes? The whole system of preparation for the army is defective The school education for the army, as for all other professions, should be that of English gentlemen and nothing more

But more unwise still is the mode of *examination* of boys for entrance to Woolwich and Sandhurst where the capacities of the candidate are not considered as a whole, but the test is restricted to the quantity of mental food he has been able to digest

The examination of candidates is biennial and takes place at various centres for convenience The whole of the candidates undergo the mental examination in various subjects for which to put it shortly the following marks are assigned 5000 in mathematics 4000 in languages and 5000 in other subjects *And not a solitary mark is allotted to physique!* By physique I do not mean size, for some of our most illustrious officers have been small made men who seem more in demand now than ever But I refer to the possession of capacious chests, good limbs general vigour and sound health

The candidates who have qualified in the mental examination and for whom commissions are available are then submitted to the ordeal of a physical examination And here I hold that an element of unfairness is discernible not from the personal action of the medical examiner or from the personal conduct of his director, but from the faulty system in vogue which permits the injustice and which requires rectification if candidates are to receive their due and the army is to secure the best type of officer For while brains are imperative in modern warfare staying power is equally necessary At this physical examination the qualified candidates who are mainly rejected are the [illegible] whom some organic defect or disease has been discovered. But there is another class which is also sometimes thrown out, and rightly so. The injustice, however, lies in the fact that neither parents nor candidates are given to understand the position. The boy may be perfectly sound in every respect, but cursed with a notoriously unsuitable or poor physique, rendering him quite unfit for a soldier's life. He is, however, rejected with some general excuse, which is eminently unsatisfactory to parents.

This error requires amendment; and I submit the following suggestions upon the point.

Inasmuch as a really vigorous physique is essential for an officer as well as sound mental calibre, it is incumbent on the authorities, in order that the most suitable officers may be secured, to follow some such course as that which I now propose, for such a course would put a spoke in the wheel of physical education at school more than any other method that could be devised; and the candidates' physique, as well as that of the nation generally from the love of imitation, improved by leaps and bounds.

The medical officers deputed to examine candidates, while not knowing the names of candidates or their position in the mental examination, should be directed to award marks, exactly as in the former examination, in accordance with the physical fitness—the maximum number of marks being 2000, being an eighth of the whole assigned, which is not erring on the side of excess to insure a good physique in an officer of the army of Great Britain. And every candidate should previously understand that the physical examination will refer not only (1) to organic defects or disease, but also (2) to general physique, notwithstanding organic soundness. In this way parents would appreciate at the threshold of his career the boy's likelihood of obtaining the total qualifying marks; in many cases the chagrin of failure would thus be avoided; and the lad's education would not be interfered with by the preparation which the army examination so unfortunately entails.

No greater difficulty exists in pursuing this plan than in examining in mathematics or languages. This physical examination, however, requires reconsideration in other aspects. For instance, directions should also be issued to the medical examiners that, while candidates should be assigned a less number of marks when physical defects, such as the albuminuria of adolescents or slight varicocele, are present these defects should not necessarily exclude lads from the army.

Having long desired to speak upon this question of the training and examination of candidates for commissions in the army I have now availed myself of the opportune moment when the subject must secure a parliamentary discussion such as it has not received for generations, in the belief that the most effective officers will now be secured, worthy candidates will not be discarded, and unsuccessful applicants will not suffer a break in their education without compensating gain to those who happily succeed.

I would finally add that in the testing of candidates insufficient attention appears to me to be given to what I may term *general* characteristics, so far as these can be detected (and they should be carefully sought for) in an examination. I mean the apparent alacrity of intelligence which may exist quite apart from largeness of knowledge and for army purposes forms the superior gift—a quickness of resource; the faculty of keen observation; the possession of common sense; and, in short, a general smartness of body and mind.—I am, Sirs, yours faithfully,

CLEMENT DUKES, M.D. Lond.,
Physician to Rugby School.

Rugby, July 19th, 1901.

"LEGISLATION AGAINST NATIONAL INTEMPERANCE."

To the Editors of THE LANCET.

SIRS,—I note with pleasure that Dr. Andrew Wilson in his letter in THE LANCET of July 20th, p. 170, does not attempt to prove a negative. He is good enough to give three reasons for declining to believe that a dragon sat curling his whiskers on the cross of St. Paul's, and very properly adds, "Now, judged scientifically, I say we have no evidence in this case that dragons exist." His attitude is admirable, and I am proud to say that it is one which I have adopted for many years. *I* say that his statement that acquirements are transmissible is wildly incredible and I ask for evidence. He refers me to the works of a number of biologists. I hope that he will forgive me when I say that I have not the time to expend on this mass of obsolete literature. I had to wade through it once and I thank heaven the task is done. But I offered in the most explicit terms to deal with any statements or arguments from the works of these gentlemen that Dr. Wilson cares to quote, and my offer still holds. Dr. Wilson replies that he did bring forward evidence. Here are his words. "He says nothing, for example, of the experiments I alluded to on the division of ova, each division reproducing a perfect animal, and yet he avers there is no evidence on my side for him to criticise." Well, but where is the evidence? I can detect only a confusion of ideas. If Dr. Wilson will tell us what character was acquired and transmitted I will deal with it. He says that I pay no heed to the authority of Spencer, Eimer, and others. As a fact I do not. Deference to authority is destructive to all scientific thought. But if the appeal be made, if we try to settle this question by counting heads, I daresay I could mention 20 authorities to one that Dr. Wilson can mention. Biologists who believe in the transmission of acquirements are now so rare that they complain that they cannot get a hearing. Dr. Wilson says that our argument is reaching the *tu quoque* stage. It is quite true. Here is the *tu quoque.* I say to Dr. Wilson, "Prove an affirmative. Out of all the millions and trillions of characters acquired by living creatures prove that *one* is transmitted." Dr. Wilson replies, "No, *you* prove a negative. Out of all the millions and trillions prove that *none* is transmitted." I am sure that the *tu quoque* is a very pretty one. Were acquirements transmitted a child might answer my demand in five minutes. Omniscience and eternity would hardly suffice to answer Dr. Wilson's demand. Dr. Wilson says: "He asks me for evidence that acquired characters are *never*[1] transmitted." Really I think the printer's devil has been at work. That question precisely Dr. Wilson asked of *me* and I can hardly find words to express adequately my sense of the outrage on logic.

Mr. Cunningham, writing in THE LANCET of July 6th, p. 51, says that I am too dogmatic. The quality of my dogmatism is by now apparent. It consists in a refusal to accept other people's dogmas when they are not supported by evidence. He says: "The question is not whether somatic cells are concerned in reproduction, but whether changes in the somatic cells may affect the powers of development, or, to use a convenient term, the determinants, of the reproductive cells." Mr. Cunningham is hardly correct. The question is not whether changes in the somatic cells can affect the germ cells, but whether changes in the somatic cells can *so* affect the germ cells that *similar* changes are reproduced by the offspring—for example, whether the amputation of a tail tends to cause a lack of tail in offspring subsequently born. Mr. Cunningham declares that excessive drinking tends to make people neurotic and that the neurosis is inherited. He says that he knows of instances in his own experience. I hope that he will let us have that evidence. For 18 months the late Research Committee of the Society for the Study and Cure of Inebriety sought it and failed. Mr. Cunningham, a distinguished biologist, is probably not familiar with the study of alcoholism and will therefore forgive me if I warn him against certain pitfalls which beset the feet of the inexperienced. It will be useless to bring forward instance of drunken parents whose children are neurotic. I can bring forward any number of instances of drunken parents whose children are not neurotic and of neurotic children whose parents are not drunken. Moreover, people naturally neurotic tend to become drunken and offspring tend to inherit the inborn traits of their parents. Mr. Cunningham lays stress on the excessive use of alcohol and says that intemperate habits are often developed after the victims have produced all their children. But insurance companies refuse to accept intemperate lives, and their statistics prove conclusively that even among these picked lives, from the age of 25 years onwards, there is a marked difference in the survival rates of abstainers and non-abstainers. He says that there is some reason to believe that the children of the aged are born old and as an example states that there is reason to believe that the younger children of a family have greater intellectual powers than their elder brothers and sisters. This, he alleges, is due to the facts that men continue to develop intellectually till late in life and that they transmit the acquirement. The whole of this statement if correct, is of extreme importance By all means let us have the evidence I may say at once however, that the statement that the intellectual powers increase till late in life appears to me more than doubtful It is probable that man's intellectual powers are greatest in childhood It is then that he makes his principal acquirements, that he is most capable of learning Consider the vast mass of information—language, reading, writing, &c —that a child acquires in the first few years of his life Later he is in a position of advantage because he is able to make use of his piled up data If I studied law for 10 years no doubt I should become a better lawyer, but I do not think that I should have greater intellectual powers

---

[1] The italics are mine.

I must apologise for the length of this letter but the fault is not mine My opponents make assertions, I am obliged not only to re-state their assertions, but to furnish rebutting evidence It would be easy to write a volume in reply to Mr Cunningham alone

I am, Sirs yours faithfully,

Southsea July 21st 1901 G ARCHDALL REID

STERTOR AND POSITION

To the Editors of THE LANCET

SIRS,—Permit me to relate an experience in confirmation of Dr R. L Bowles's views[1] with regard to the value of position in relation to stertor and threatened asphyxia

A good many years ago about 1883 Dr Bowles published a short paper on this subject in (I think) the *British Medical Journal* I was at the time in charge of the General Hospital, Singapore and shortly after I had read the paper referred to a Chinaman (a police prisoner) hanged himself one day in the lock up attached to the native ward The apothecary, Mr Wheatley was soon on the spot and he cut the man down (he was unconscious and nearly dead from suffocation) bled him and succeeded in putting him apparently in a fair way to recover That night I went out to dinner, and on my return, about 11 or 12 o clock perhaps I followed my invariable custom and before going to my quarters walked through the wards of the hospital On visiting the lock up, which was a space railed off from the end of the main ward, I found the Chinaman on the floor resting only on his head and his heels livid unconscious breathing stertorously with his mouth and pharynx full to overflowing with frothy liquid With Dr Bowles's paper fresh in my mind I turned the man well over on his side and kept him in that position A quantity of fluid escaped from his mouth and nostrils the stertor ceased, breathing became natural consciousness gradually returned and he recovered I am confident that but for my accidental visit the man would have died very shortly There was, I remember a native policeman on duty who had looked on but had not thought it necessary or worth while to call for assistance

This case, in which the patient was undoubtedly saved from imminent asphyxia from fluid in the air passages, may be contrasted with the case of hanging noted in Dr Bowles's second lecture in which the result the patient not having been turned on his side, was not so fortunate

Since that time I have employed Dr Bowles's method in many cases of stertorous breathing with success as regards the stertor though as regards the actual saving of life I can recall no case so marked as that given above for too often the causes of stertor are themselves the causes of death If however, the stertor can be stopped it is sufficient reason for the treatment for at the least it helps to procure euthanasia, possibly for the patient, certainly as regards the feelings of the friends who otherwise might have to hear the horrible sound for hours With the exception of Dr Bowles's former paper I have never seen anything written on the subject and have sometimes thought that the treatment is not very widely known or at all events very widely practised, it is a good thing therefore that Dr Bowles has again brought the matter to notice in his lectures which you have lately published —I am Sirs, yours faithfully,

MAX F SIMON
Late Principal Civil Medical Officer Straits Settlements
Welbeck street W July 29th 1901

THE INHALATION OF FORMIC ALDEHYDE IN THE OPEN-AIR TREATMENT OF TUBERCULOSIS

To the Editors of THE LANCET

SIRS,—In your issue of August 3rd 1901, p 310 your reporter in his report of the proceedings of the Tuberculosis Congress has inadvertently substituted Dr R. Maguire's name for mine It was I who read the paper on the Inhalation of Formic Aldehyde in the Open air Treatment of Tuberculosis at the Congress Will you kindly correct this error and oblige Yours truly

CHOWRY MUTHU

Inglewood Sanatorium St Lawrence I W,
August 6th 1901

To the Editors of THE LANCET

SIRS,—In your last issue a paper was attributed to me as having been read at the Tuberculosis Congress which was not mine The mistake was the more unfortunate as the paper expressed views exactly opposite those expressed by me My paper stated that inhalations could have no effect on the tubercle bacillus, and that I had demonstrated that the intravenous injection of methylic aldehyde by my method even to the amount of 50 cubic centimetres, was entirely devoid of danger

I am Sirs yours faithfully

August 6th 1901 ROBERT MAGUIRE.

OPEN-AIR TREATMENT OF PULMONARY TUBERCULOSIS

To the Editors of THE LANCET

SIRS —In your reference to my communication to the Medical Section of the British Congress on Tuberculosis published in THE LANCET of August 3rd p 307, there occurs a statement which appears misleading from my point of view and which I crave your indulgence to correct I am reported to have said that the temperature of a sanatorium ward was "best kept not too high" This is likely to convey a view very different from that which is held by me and was elaborated in my remarks I allow the freest access of fresh air to the patient day and night, at all seasons taking care that he is sufficiently clad I am not careful as to the temperature of the surrounding air, whether in or out of doors Indeed there seems a disadvantage in endeavouring to combine free exposure of the patient out of doors with his occupancy of rooms in which the temperature is maintained constant or still worse which may become overheated It is more logical and experimentally more successful to subject the patient indoors to approximately the same conditions as out of doors It is wise to be sparing in respect of artificial heating

It is an interesting commentary on this statement to add that the results during the past eight years have proved themselves in many respects more satisfactory in winter than in summer Even with the most delicate patient I have on no single occasion observed a bad result follow the most complete exposure to such influence Contrariwise in proportion as the patient is more freely exposed the satisfactory result is attained more quickly During the present spring, for example I have allowed a considerable number of patients not only to be out all day, but to sleep outside all night merely under cover of a three foot-deep shelter completely open in front. Some of these patients literally ran ahead as compared with others sleeping in doors

I am Sirs your faithfully

Edinburgh August 3rd 1901 R. W PHILIP

"BRITISH MEDICAL MEN AND GERMAN WATERING-PLACES"

To the Editors of THE LANCET

SIRS —The correspondence recently published in your columns[1] raises a question of importance at this season when so many betake themselves to health resorts It is one which cannot be settled without the due appreciation of certain incontestable facts While we have in this country springs such as those of Buxton, Harrogate, Strathpeffer, Cheltenham, Leamington, Tunbridge; and Bath, which can hold their own, or should hold their own, with continental waters of like character, it must, I think, be admitted that, rich as Great Britain is in minerals, nature has not provided this country so lavishly with mineral waters of potent constitution and high and regulable temperature as she has some portions of the continent.

---

[1] THE LANCET July 20th (p 1[illegible]1 and 27th (p 22[illegible]) 1901.

It is true that deficiencies of temperature and mineral constitution may be artificially supplemented, but for such baths, and merely as such, there is no necessity for going even to English watering-places. They may be had in one's own house, but without the necessary adjunct of that holiday sense of relief which can only be obtained *procul negotio.* This consideration of holiday entertainment is an important one. Our variable climate, and perhaps our national characteristics, seem not to have been so favourable to the cultivation of those powers of entertainment which the more steady climate of the continent and the less insular reserve of its inhabitants have fostered. These differences seem to have led to the establishment of a reputation for "curing" and at the same time "amusing" which accounts satisfactorily enough for our watering-places having been robbed of many English visitors. The physical differences cannot, of course, be removed except by artifice, and Dr. Thomas Dutton acknowledges that certain German springs are more potent in the relief of some diseases than their English equivalents. Much as has been done, moreover, to render English resorts attractive, still more will have to be done in some cases before the level of continental brightness and "go" is reached. Many who betake themselves to such places are in no sense invalids and merely need to be amused. Others are only slightly indisposed. It is this fact which would render it difficult to prove by statistics even the particular contention of Dr. W. Bezly Thorne. It is undoubtedly true, as Dr. Dutton maintains, that many cases of heart disease are better treated by recognised means in this country than by going abroad. Constant experience in our hospitals and among the poor proves this beyond dispute. It is also true that a very large number of persons who go abroad for cardiac treatment suffer from little else than general fatigue and return refreshed and invigorated after a quiet holiday combined with carefully administered baths and regulated exercise, and crowned by a short stay in a bracing climate. In this category I should place cases of slightly disturbed compensation in organic disease of the heart. But will anyone maintain that the waters of Abana and Pharpar—of Buxton, Harrogate, or Scarborough, and a dozen other places would not be equally efficacious in the majority of these cases? Were the statistics of all such cases placed against those of grave organic lesion with much disturbed compensation arithmetic would undoubtedly be with Dr. Thorne, but Dr. Dutton's contention would not be invalidated. It is more easy to detect cases not grave enough to be sent abroad than those grave enough to be *safely* sent abroad. But to send such patients from home may be the duty of the physician if a given spa on the continent be naturally superior to our own for a specific purpose.

I am, Sirs, yours faithfully,
ALEXANDER MORISON, M.D. Edin.
Upper Berkeley-street, W., August 5th, 1901.

"THE TIMES ARE TROUBLOUS."

To the Editors of THE LANCET.

SIRS,—As a general practitioner in London I should like to say a few words to indorse the opinions set forth in the letter of "G. P." under the above heading which I have just read in THE LANCET of July 27th, p. 229. The two evils of which he speaks—viz., the abuse of the out-patient department of hospitals and the prescribing chemist—are very real and very serious ones to us general practitioners. The loss resulting to the medical man from the former can be more especially appreciated by those who, like myself, reside in the near neighbourhood of a large general hospital, the out-patient rooms of which are every day filled to overflowing with patients, a very large proportion of whom would be well able to afford the moderate fees charged by the medical men in the district. If such a plan as that suggested by "G. P." of excluding all such patients from hospital charity as are not actually recommended by medical men were followed the chances of lessening the evil would be very greatly increased, and the number of undeserving cases admitted would be at once reduced to a minimum. With regard to the prescribing chemist, he is a very thorn in the flesh to the general practitioner. One need but wait for a few minutes in any chemist's shop at almost any time of the day to understand why, at a time when coughs, colds, and sore-throats are rife, the medical man has so comparatively few patients on his list afflicted with these maladies. Surely with a little effort something can be done to check this growing evil; if the practice of counter prescribing be illegal, as it undoubtedly is, there should be no great difficulty in putting a stop to it. For obvious reasons this cannot be done by individual action—it is a matter which should be combated by the profession as a whole, and what more natural than that we general practitioners should look for aid, as "G. P." suggests, to our representative body—our General Medical Council—and should call upon the members of this body to act for us and with us in making an earnest effort to stamp out a practice which is becoming more and more a source of loss to the already not overpaid members of an honourable profession. It is in the hope that this matter will be taken up seriously by the profession, and that the suggestion offered by "G. P." may bear much good fruit, that I am writing this letter in which my aim has been simply to uphold the views of that writer rather than to make any further suggestions of my own.

I am, Sirs, yours faithfully,
M.B., CH.B.
July 20th, 1901.

To the Editors of THE LANCET.

SIRS,—That there is considerable abuse of hospitals in London there is no doubt. But then, are not the means of obtaining a knowledge of the financial position of the applicants for charity totally unbusinesslike and inadequate? I submit that in nine cases out of 10 the statement to the effect that "I can't afford to pay a doctor" is considered an adequate answer. I would like to ask if any other charitable institution or Poor-law authority grants its benefits under similar circumstances. The answer is no, and why should medical charities be so foolishly weak, encourage deception, and tend to ruin

THE MEDICAL BROTHERHOOD?
August 5th, 1901.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The Plague Epidemic.—Mr. Haffkine on the After-effects of Inoculation.—Chaulmoogra Seeds.—Strike of Medical Students in Bombay.—Changes in the Indian Subordinate Medical Department.—The Infection of Malaria.—The Famine.—Kala-azar in Assam.—Emigration from India.

A FURTHER rise has taken place in the plague mortality throughout India. For the week ending July 13th there were 1258 deaths, as compared with 1125 for the previous seven days and 200 for the corresponding week last year. The increase is almost entirely in the Bombay Presidency where 1048 deaths were reported. Bombay city had 85 deaths and Calcutta 16. Karachi has been declared no longer infected with plague. There were only two deaths in Bengal, three in the Madras Presidency, and six in the North-West Provinces, but 97 deaths were returned from the Mysore State. An outbreak has occurred in Tongkah in Siamese territory and it has therefore been declared an infected port.

A lecture was recently given at Poona by Mr. Haffkine on the After-effects of Inoculation. Rumours have been spread abroad from time to time by ignorant and malicious persons that inoculation for plague produced other diseases. Mr. Haffkine very clearly proved the baselessness of these rumours. He seems to try to show, however, more than this—viz., that there is a comparative freedom from sickness and disease amongst the inoculated for some time after the operation. The statistics given by Mr. Haffkine certainly seem to show a lessened mortality from general diseases amongst the inoculated which is difficult of explanation. At any rate, the examination of whole groups of inoculated and uninoculated persons living together and belonging to the same races, castes, social position, and families, has clearly shown that the inoculated have not suffered from the operation. It is not generally known that serum from cases of human plague has been tried as a curative agent, but from the notes shown to me there was apparently no benefit obtained. The doses were small—three cubic centimetres and five cubic centimetres once a day and not always that—so this may possibly be the explanation.

It may interest your pharmaceutical readers to know that the source of the seeds known as "chaulmoogra" which are largely used in native medicine as well as in Europe and which have usually been attributed to the species known as gynocardia odorata, is the species known as taraktogenos kurzii and not the tree known as chaulmoogra. This decision has been arrived at by Dr. Watt, the Reporter on Economic Products.

A curious strike of medical students on a large scale is going on in Bombay. The army students and the lady students are taking no part in it. Some offensive writing on the walls was brought home to certain students who were singled out for punishment but who seem to have obtained the sympathy of a large number of the college students. The principal appears to have adopted the punishment of refusing to sign certificates as to moral character, which loses for the culprits the period of a year's study. The strike followed.

Further changes in the organisation and prospects of military assistant surgeons in the Indian Subordinate Medical Department have been made in order to provide an adequate reserve for war or other emergency. These officers will be required for military appointments, for duty with store depôts, marine and telegraph departments, for provincial and railway appointments, and for the formation of a reserve of 15 per cent. of the total for temporary duties and to fill leave vacancies. The pay has been increased and the prospects have improved all round.

A very instructive incident occurred at the Kallang extension works in connexion with an outbreak of malaria. The Javanese workmen had been free from fever until the arrival of a number of Punjabis. These Punjabis were many of them suffering from anæmia and had enlarged spleens. Some Chinese who were also employed turning up the soil escaped. The quarters of the Javanese and Punjabis were adjacent to each other and specimens of anopheles mosquitoes collected from their buildings show them to contain the malarial parasite. It appears, therefore, that the disease was introduced by the Punjabis and conveyed to the Javanese coolies by the mosquitoes. The mere turning up of the soil did not seem to affect the Chinese and they were quartered further off. The disease has apparently been checked by the employment of mosquito curtains, the distribution of quinine, and extensive lime washing. A correspondent of the *Madras Mail* shows that the value of the castor-oil plant against the trouble of mosquitoes lies in its attractiveness for mosquitoes which seem to obtain some nourishment from it. If placed therefore some distance off not even the light of a lamp will attract them away from it. To have a castor oil plant near a sleeper is simply to attract the insect towards him.

The famine returns still show over half a million persons under relief. The monsoon prospects continue to be unfavourable and the rainfall in the areas which want it most has been up to the present very scanty. There has been no rain in Baluchistan, only 26 per cent. in Gujerat, 30 per cent. in Central India, and only 33 per cent. in Upper India.

The peculiar fever of Assam known as kala azar appears to be dying out. The deaths have fallen from 18,597 in 1897 to 9012 last year, but the annual report on the dispensaries in Assam shows an extraordinary increase of skin diseases.

There is a steady emigration of Indian coolies to the various colonies every year. Demerara takes most, but Natal and Fiji as well as Mauritius and Trinidad import them. The total number recruited last year was 18,489. They chiefly go from the North-West Provinces and Oudh. Those returning from Demerara brought back savings on an average of Rs. 139·8 per head; those from Trinidad had an average saving of Rs. 214 per head. The immigrants into Natal seem however to be the best off and to make the largest remittances. The Government of India takes a very fatherly care of all these people and looks well after them.

July 20th.

THE ORGANISATION OF THE PROFESSION

(FROM OUR SPECIAL COMMISSIONER.)

Adoption of a New and Democratic Constitution by the British Medical Association.

It has often been said that medical men are not good business men and certainly the meeting of the British Medical Association at Cheltenham does not belie this impression. On this occasion there were business matters of the utmost importance to be discussed and settled, but garden parties proved far more attractive. A complete revolution has been accomplished by a mere handful of members while the immense majority of the members of the British Medical Association who went to Cheltenham were content to leave all business matters to take their chance. It is doubtful whether any other corporation, professional, scientific, commercial, or trade association would have manifested so much apathy when such important issues were at stake. If the new constitution which has been adopted is worth the paper on which it is written such indifference will never again be witnessed at the annual meetings of the British Medical Association. In future these annual meetings will be attended not merely by members on picnic thoughts intent but by duly elected and paid representatives bearing imperative mandates instructing them how to vote. It is to be presumed therefore that henceforth the business of the Association will be attended to by representatives imbued with the sense of a duty to perform and really qualified to speak on behalf of a large proportion of the practitioners of this country. The paucity of members present to discuss what was qualified on the agenda as the report of the Constitution Committee but what in reality promised a complete revolution of the Association may be explained by the fact that old habits continued under the new order of things. The members evidently utterly failed to realise that there was a new order of things. Formerly the Council of the Association did not believe that they were legally bound to carry out the instructions voted at the annual meetings. As was officially explained the Council had always striven to act according to what they conceived to be the desires of the majority of the Association. But on many occasions they did not consider that the majority vote of a general assembly at the annual meetings represented the majority of the Association and therefore they did not carry out the instructions given. Consequently the utility of adopting resolutions at such general assemblies was more than doubtful, and, presumably, the members grew weary of recording mere pious wishes. Under such circumstances it is not surprising if the rival attractions of garden parties proved a powerful allurement. There was, however, no such excuse at Cheltenham. This time it was fully understood and broadly stated that the Council of the Association have all this while been labouring under a misapprehension and that however poorly the general assemblies at the annual meetings may be attended these assemblies are sovereign and the Council is legally bound to carry out their decisions. That the Council for so many years should have been mistaken as to its legal position and responsibilities constitutes yet further evidence of that lack of business capacity which is widely acknowledged and deplored. Have a few strokes of the pen, a number of votes hastily recorded by a few persons altered all this?

Undoubtedly it is somewhat difficult to believe in the possibility of such a sudden transformation scene. It is all a question of ripeness. Has the day really come for the harvest? Mr. Edmund Owen who reported for the committee appointed to draw up the new constitution, described the ripening of his own mind. He made a most able, humorous, and sarcastic speech. He related that his opinions were not known when he was put on the committee, in fact he did not know them himself, he did not even know that there was a question on which he ought to have an opinion. There is every reason to fear that Mr. Owen was not alone in this state of ignorance, but that even to-day, and in spite of the Cheltenham meeting, this is precisely the position of perhaps the majority of medical men throughout the country whether they belong to the British Medical Association or not. Now, however, that the constitution proposed by the committee—of which Mr. Owen was chairman—has been adopted a good deal more light will be thrown on the subject. To begin with, the unattached member is to be abolished and henceforth every member must join a local branch of the association. Then he must pay 25*s.* instead of a guinea annually. Such a change cannot be effected in silence. Every member who still ignores what has occurred will ask why these alterations have been effected. Some of the members who were formerly unattached to any branch may now that they are forced to join a branch be induced to attend some of its meetings. Then the branches will have to elect representatives, and all this will lead to discussions and explanations and t[illegible] Will this increase of activity and [illegible] the membership of the Association or will it frighten any considerable number of members away? It is difficult to find anyone who is bold enough to prophesy. In any case, the complaints have been loud and long that the British Medical Association did not do anything in regard to the political and economical concerns of the profession. There is the battle of the clubs. The British Medical Association is strong enough and sufficiently numerous to settle that grievance if all its members were disciplined and if they acted in common accord. As yet nothing practical has been done by the Association. Where the battle has been fought it has been fought by small local bodies acting independently of the Association as a whole. The object of the new constitution is to convert the Association into a *fighting* body and to make it take the lead in such matters. There are a few medical unions in this country; their history and militant action have been described at great length in these columns. But these 30 or 40 medical unions or guilds represent only a very small *minority* of the medical profession. It was said that the conference on the organisation of the profession held at Manchester last year represented some 4000 practitioners, but these practitioners were not all in union, at least not in the stricter sense of the word. It is, indeed, because they were so weak, as compared to the great bulk of the members of the profession who remained apathetic, that the idea of capturing the British Medical Association arose, and so far as the voting and carrying of resolutions goes this idea has now been fully realised.

What, however, will be the upshot of these votes? Can the life, habits, mode of action—or rather of inaction—of 16,000 or more practitioners be altered by the votes of less than a hundred among them? If they are really ripe for such a sweeping change then this most audacious attempt may very well prove successful. On the other hand, the fact that five out of six, or perhaps six out of seven, of the medical men who were enrolled as members of the Cheltenham meeting did not take the trouble to participate in the votes or discussion which were to decide their fate does not indicate that their opinions had been ripening. Perhaps, however, those practitioners who feel where the shoe pinches and therefore could not afford to be at Cheltenham, have a far keener appreciation of the importance of the points at issue. It is these absentees who will govern the future meetings. The voice of the poorest practitioner will be as powerful as that of the most wealthy and successful in the election of the future representatives. The Council will no longer be the governing body; its functions are now reduced to that of an executive appointed to carry out the instructions of a representative parliament. This revolution was graphically described by comparing the British Medical Association to a pyramid which stood on its point. The few governed the many. Now the whole thing is reversed and the pyramid is to stand on its broad base and the many are to govern. There is to be proportionate representation. As a rule, and for the more rapid transaction of business, the vote will be by show of hands; but, when desirable, the vote will be taken by card, and "every representative shall record as many votes as there are members in the division or group of divisions which he represents." Then when any constituency has passed a vote on a subject the representative of that constituency must vote in accordance with such resolution whatever his own personal opinion may be. *This* is delegateship and what is termed on the continent an imperative mandate. An amendment was moved to the effect that it was better to call a spade a spade and that therefore the word "representative" should be struck out and the word "delegate" used in its stead. This proposal, however, was outvoted. But if the word "representative" is retained this is done as a matter of tactics rather than of *principle*. A representative is supposed to act according to his own discretion; a delegate must obey the orders of his electors, and the whole wording of the clause clearly indicates that it is delegates and not representatives that are to be elected. Here, again, the question arises whether this discreet veiling of the meaning of the clause is not an indication of the fear that the Association is not ripe for the great democratic revolution that has been accomplished.

On the first day of the discussion on the new constitution there was but a small attendance, composed mainly of the friends of the proposal. Consequently there was very little opposition, comparatively little discussion, and but few amendments. The movers of the amendments were promptly out-voted and in a sitting that lasted only from 2.30 to 5 P.M. 15 clauses with several sub-clauses were adopted. There was certainly some grumbling. It was said that the whole thing was being rushed through, the real fact being that as there was hardly any opposition or even friendly criticism it was easy to progress rapidly. Then it was rumoured that the alarm would be sounded and that the next day the members would come in force to see that their fate should not be decided in such helter-skelter haste and without more careful examination, criticism, and debate. The proceedings on the following day commenced with an address by Sir William Thomson, C.B., on surgery, with special reference to the South African war and the Princess Hall was certainly well filled. It did seem as if this time at least the latter half of the new constitution would be discussed by a more imposing number of members. But no sooner had Sir William Thomson finished his address than a good half of the members present rose and left. Of those who remained the greater part dwindled away one by one. Towards the end of the sitting Mr. H. Nelson Hardy proposed that a recommendation should be made in favour of appointing a committee to advise the editor of the *British Medical Journal*. This met with considerable opposition and it was necessary to count the votes. There were 22 votes for and 20 against. These figures give some idea of the paucity of the attendance. Subsequently there were barely 30 members in the body of the hall and still the clauses of the new constitution were being carried one by one, and this so rapidly that the greater part were not even read out, but their number and heading alone were given. As there were 36 such headings remaining to be voted upon in the course of one single afternoon it was certainly necessary to proceed rapidly. Indeed, the lengthiness of this constitution seems to have frightened a good many members away. To grasp the meaning and bearings of so many rules, details, sections, and subsections was a formidable undertaking, and the weather was very hot.

If it were possible to look upon this project of a constitution in the light of a Bill before Parliament a speaker very justly observed that it would require three or four sessions of the House of Commons to pass such a constitutional enactment. Yet here the whole thing was done in two sittings or about, in all, four and a half hours. Certainly the committee which had prepared the scheme had worked admirably, and had held nine sittings which were well attended. It also evolved within its own ranks a real statesman, Mr. J. S. Whitaker of Yarmouth. At Cheltenham Mr. Whitaker acted as a Prime Minister steering a Government Bill through Parliament. He was ever ready with a concise, lucid explanation which swept away misunderstandings and doubts. His master grasp of the whole subject commanded unbroken and patient hearing. In manner modest, he was yet as firm as a rock, and he courteously but fearlessly criticised men who were much his seniors and have been at the head of the profession for years. If any one can make the new constitution a living reality it is Mr. Whitaker, but there is a weakness even here. Mr. Whitaker's experience is that of Yarmouth, where the profession is admirably organised and unanimous. Such favourable surroundings may make him a little over-confident as to the possibilities elsewhere. The apathy shown at Cheltenham is not encouraging.

Not only had this most important new constitution to be discussed and decided, but, what was quite as important as the adoption of the constitution, this was to be followed by the bringing forward of certain motions which would be a commencement in the practical application of the new order of things. One motion condemned the Midwives' Registration Bill and the other was to impose on all members of the British Medical Association a pledge which would debar them from accepting any post resigned by a fellow member with the approval of his branch. This, of course, is the first principal of unionism. In vulgar parlance it abolishes undercutting. It is the first step that can be taken in fighting the battle of the clubs, but the members of the British Medical Association seemed so little concerned about the battle of the clubs that there was hardly any one remaining in the hall when the matter came up for discussion. Indeed, both motions had to be abandoned because it was rightly felt that it would be ridiculous for such far-reaching principles to be sanctioned by only from 30 to 40 members. This dismal conclusion of what should have been a great and historical sitting is certainly most disconcerting. A new constitution is voted involving very radical changes. Then follow one or two test motions which were to show that the new constitution would be applied in the spirit and direction intended by its principal promoters. This was most critical and more important in a way than the constitution itself, for after all paper constitutions are of but little significance, the whole question rests in their application. It can be understood that some members should have shrunk from the irksomeness of discussing the lengthy and minute details of the new rules, but when it came to the practical question of their application then it was natural to expect that the members would come up in great force. Instead of doing so they allowed the meeting to collapse and in the face of an empty hall the motions which from their practical bearing were the most important of all had to be abandoned. If at these annual meetings anything is to be done affecting the economical interests of the profession it is indeed time that the meetings should be differently constituted. There must be something better than garden-party government and if anything can secure that end the new system of representation by delegates and proportional voting should do it. The future now depends on the constituencies themselves.

THE WAR IN SOUTH AFRICA.

(BY A SPECIAL CORRESPONDENT.)

THE signs of a conclusion of this lingering campaign are slowly but surely becoming more evident. The Boers seem to confine their offensive tactics to the wrecking of a train here and there as circumstances permit, and for the rest they watch our camps and columns from a safe distance and attempt to evade any force sent against them, only fighting when escape is otherwise impossible. The winter is a severe one and the cold nights have a telling effect upon the endurance of even the hardy Boer. Within the last week four prisoners were captured at Brandfort with one boot between them and at the same place it is rumoured that 40 men surrendered because their clothing was not sufficient to protect them from the rigour of the South African winter.

At Cape Town the number of plague cases is diminishing and there seems every prospect that the disease will shortly be stamped out by the energetic means adopted by the medical officers in charge. But whilst the plague is disappearing another annoyance is increasing in severity. Cape Town is rapidly becoming the happy hunting ground for thieves and loafers of all descriptions. All the principal hotels find it necessary to warn their visitors to keep the doors of their rooms locked and even then thefts occur, a wrist watch in one instance being stolen whilst the owner was absent for 10 minutes in his bath.

The discomforts and dangers of travelling on the railway are very numerous. One never knows whether or not there is a dynamite bomb laid under the rails, and in some instances, as at the mishap to the Gordons on the Petrusberg line, the Boers hide themselves within easy range of the site of the accident and shoot the men down as they emerge from the wrecked carriages. In some instances, owing to the destruction of the line in front, the trains are delayed at some insignificant siding where neither food nor drink can be obtained, and the unwary traveller who has not provided himself with a hamper of good things may have to go to bed supperless. Travelling by night in some districts has to be stopped, and the journey from Cape Town to Pretoria takes on an average four or five days instead of 48 hours, which is the usual time taken in times of peace. I recently took eight days to accomplish the journey.

The work of devastating the country, disagreeable as it is to all engaged upon it, is proceeding with certainty. Thousands of sheep, cattle, and horses can be seen collected on either side of the line in immense herds of hundreds of thousands; in some cases one passes by an immense herd nearly half a mile in length slowly and wearily marching to some centre such as Bloemfontein or Pretoria with scarcely a blade of grass and very little water to cheer them on their way. Hundreds of sheep and lambs die on the way from want and exposure. At this time the veldt is almost denuded of any fresh verdure and all that the cattle can find to eat is the grass which has been roasted by the previous summer's sun into a kind of dried hay. Veldt fires are ignited to render the country unfit for the Boers to live in and large tracts of country have been and are being laid waste by this means. It seems to be a common custom in this country to fire the grass early in the winter to give the veldt a chance of coming up fresh and green after the next rainy season, but the fires now are of much larger dimensions than is usual.

The hospitals are everywhere fairly full, but in all there are a certain number of empty beds. The outbreak of enteric fever this year has not been of such proportions as it assumed in the autumn months of 1900. Perhaps this may be partly explained by the fact that a certain proportion of the men in the field have been protected by a previous slight attack from a second infection and from the fact that there is not the same need for haste and of taking long marches on short rations.

The Imperial Yeomanry Hospital at Pretoria is in a flourishing condition. Small convoys of sick and wounded arrive daily. Owing to stress of work in Pretoria Dr. Richmond has been requested to take up duties at the Imperial Yeomanry Hospital there instead of proceeding to Elandsfontein, where a small branch hospital of about 50 beds has been equipped and opened. At present it is intended to keep this branch hospital more as a convalescent camp and for cases of slight ailments, the more serious cases being sent at once to Pretoria.

The chief diseases in evidence are rheumatism, malaria, influenza, and tonsillitis, with cases of heart disease and minor ailments. Enteric fever and dysentery crop up every now and then, but the number of fresh cases is certainly decreasing. The new Yeomanry are not such fine men as their namesakes were either in physique or in general bearing. There seems to be a desire amongst some of them to gravitate to hospitals as the safest and pleasantest places of resort. Such cases of malingering would at once be met by an order which should compel a man to lose his pay of 5s. a day whilst in hospital unless he was specially recommended by his medical officer as a deserving case. It is one of the most difficult things in the world to be sure that a man is malingering and in any case it takes several days of careful watching to make quite sure.

Owing to the absence of any heavy engagements the amount of surgery to be done is not large and it depends chiefly upon accidental injuries, entailing railway accidents, and minor surgery such as abscesses and piles. Hernia and varicose veins are fairly numerous, but owing to the time which must elapse after operation before the patient can resume any active duties it becomes a question as to whether it is advisable in many cases to perform radical cure.

Deelfontein, July 10th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Hospital Sunday and Saturday Fund.

A MEETING of the General Committee of the Manchester and Salford Hospital Sunday and Saturday Fund was held on July 24th. The Sunday collections amounted to £4180 16s. 10d., those on the Saturday (to date) to £3829 12s. 11d., and a balance of over £200 from last year together with bank interest brought the total to £8270 10s. 4d., which the expenses, £556 2s. 5d., reduced to £7714 13s. 11d. It was estimated that about £100 would still be obtained from later Saturday collections and the committee decided to distribute £7600 amongst the medical charities, which is an increase of £1000 over last year's distribution. Manchester, unfortunately, does not approach Liverpool in regard to this special [illegible] of charity.

The Heat and the Drought.

Like most other places in the country Manchester has had its share of hot and dry weather. Perhaps the shade temperature, 88·2°F., recorded on July 20th may prove the highest of the season. The mean temperature of the third week in July was 7° higher than the average of the mean for the corresponding week for the previous 10 years. The mortality rose from 16·9, the average for the previous six weeks, to 20·1. The long-continued drought came to an end on July 25th. It was beginning to be felt seriously and Manchester was put on a shortened allowance of water, notwithstanding the supply from Thirlmere, without which, indeed, it would have been in a much worse case. On one occasion 320,000,000 gallons were added to the reservoirs of Longdendale. The rainfall on that day, as observed at St. Bede's College, for the 24 hours from 9 A.M. on the Thursday to 9 A.M. on Friday, was 2·62 inches, the highest, it is believed, ever recorded for Manchester, and higher than the total for any single preceding month of this year, March and April approaching it most nearly. Curiously enough the rainfall at Longdendale among the hills was half *an inch less than at Manchester, quite reversing the usual* order of things.

The Milk-supply.

The drought has told heavily on the milk-supply, greatly increasing the cost of production, and a meeting of the Cheshire Milk Producers' Association was held at Crewe to consider the question of price and also that of the new milk standard which came into operation at the end of the month. This directly affects Manchester which is very largely supplied from Cheshire and Derbyshire. It was said that present prices did not pay the cost of production, and a resolution was passed appointing a committee from the meeting to meet the milk-dealers of Liverpool, Manchester, Birkenhead, and other towns, and to try to get better prices. Any rise in the price of milk is always to be regretted in the interests especially of the young, but farmers can scarcely be expected to supply it at a loss. As regards the new milk standard a resolution was passed objecting to samples being taken for analysis "after the milk has left the farmers' control" and urging that they should "be taken at the loading station," which seems to be a reasonable request.

Medical Relief and Civil Rights.

At the last meeting of the Manchester Board of Guardians a resolution was passed "in favour of asking the Local Government Board to urge on the Government the desirability of amending the law which prevents persons who are, or who have been, in receipt of medical relief in workhouse infirmaries from voting in Parliamentary or municipal elections." It will be sent to other boards of guardians with a view to concerted action. A letter was received from the president of the Poor-law Officers' Association calling attention and objecting to the condition required by many of the boards of guardians that married couples required as officers shall be without children, *alias* "encumbrances." The board agreed not to use the words in advertising for married officers. The presence of children would no doubt lessen the temptation to drinking among the couples who are now perforce childless.

July 30th.

LIVERPOOL.

(From our own Correspondent.)

The Housing Problem in Liverpool.

For some time past the Housing Committee of the Liverpool Corporation have had under consideration a large scheme for re-housing persons who will be dispossessed by the demolition of about 8184 insanitary houses. The committee have issued their report, in which they state that the number of insanitary houses is now 7500, consisting of 750 houses erected since 1842 and contained in, or abutting on, courts; and 6750 back-to-back houses, erected prior to 1842, having no through ventilation and contained in courts with narrow entrances. Of this number about 15 per cent. are derelict or in respect of which a closing order might be obtained as unfit for human habitation; and this deduction left the number to be dealt with as about 6400. The cost of demolishing these houses might be estimated at £279,000, which sum included the cost of acquiring the sites. With regard to the re-housing adequately of the persons who will be dispossessed it appeared to the committee that they ought, as the work of demolition proceeded, to provide for all those of the dispossessed who would require re-housing by the corporation. The committee estimated that this would involve the erection of 4800 houses, and that it would not be safe to assume as the cost of erecting these a less sum than £720,000. In the letting of these houses the committee proposed to continue the policy which they had already adopted—viz., to accept as tenants those who have been or were to be dispossessed. The committee had already built, or were about to build, 903 houses in 12 streets. They would thereby be in a position of having houses always ready for dispossessed tenants until the work of demolition was completed. With regard to the cost to the ratepayers of the work yet to be done by the committee, assuming that a period of 60 years only was obtained within which to repay the amount borrowed for the purpose, and assuming that the cost of demolition would be £529,000 and that the estimated cost of re-building would be £720,000, the annual charge would be £64,531. From this sum must be deducted £25,000 in respect of the net rents to be received, leaving an annual charge on the rates of £39,531.

The "Celtic" and the Liverpool Hospitals.

The leviathan White Star liner *Celtic* was open for public inspection on July 24th for the benefit of the hospitals, 5,162 persons visiting the ship. The receipts amounted to £258 2*s*., the whole of which will be divided amongst the David Lewis Northern Hospital, the Stanley Hospital, and the Bootle borough hospitals in equal proportions. These institutions are mostly used by employés of the White Star Company.

August 6th.

WALES AND WESTERN COUNTIES.

(From our own Correspondents.)

Newport and Monmouthshire Hospital.

The Newport and Monmouthshire Hospital, which was formally opened by Lord Tredegar on August 5th, is a three-storey brick building with Bath stone facings, and is situated in the town of Newport within grounds about five acres in extent presented to the trustees of the hospital by Lord Tredegar. The out-patient block is placed close to the entrance to the grounds and is quite distinct from the main buildings which stand back from the Cardiff-road nearly 100 ft. There is a total accommodation for 84 patients in six 12-bed and 6 two-bed wards;. 14 beds will be used for male medical cases, 14 for female medical cases, and 14 will be allotted to children; 28 beds will be available for male surgical cases and 14 for female surgical cases. The central block of the hospital is devoted to administrative purposes and on either side are the male and female ward blocks connected with each other and with the administrative block by corridors. On the ground floor of the central building are the house-surgeon's bedroom, bathroom, and sitting-room, the matron's sitting-room and office, the board-room, porters' rooms, and a bathroom. On the first floor are 14 nurses' bedrooms, each 14 feet by nine feet, a nurses' sitting-room and dining-room, a bathroom, and the matron's bedroom, leading out of which is a separate bathroom. On the second floor are the kitchen, the scullery, and the pantries, nine servants' bedrooms, and a servants' hall. The arrangement of each of the ward floors is similar; one description will therefore suffice for the six. There is on each floor one large ward, 11½ feet in height, 50 feet long, and 26 feet wide, intended for the accommodation of 12 patients with an air-space of 1245 cubic feet for each. Eleven of the 12 beds have a window on each side. The walls are covered with Parian cement and painted, and all corners are rounded. Between the beds there are plug connexions fitted in the wall to enable a portable electric light to be used for special examinations. The heating of the large ward is by means of a double-fronted central stove with descending smoke flue and a fresh-air flue, and by hot-water radiators. The sanitary offices are in a corner annexe approached by a cross-ventilated passage. The slop sink of Messrs. Dent and Hellyer is of the fountain pattern for which is supplied a separate cistern—a precaution not always observed where this type of closet is fixed. The nurses' duty room adjoins the large ward and has an observation window in the dividing wall. There are also a patients' bathroom fitted with a porcelain bath, store cupboards, nurses' water closet and lavatory, a two-bed isolation ward, and a convalescent room made particularly attractive by the addition of a corner bay window from which on the upper floors an extensive view across the Bristol Channel can be obtained. The operating theatre is on the ground floor close to the patients' entrance; it has a north-west aspect and is lighted by windows and a top lantern light. The walls are of Parian cement painted white and the angles are rounded. There is an anteroom for the giving of anæsthetics. The floor is of terrazzo sloped towards an opening at the floor level. One of the glazed porcelain sinks has treadle action water fittings. Hot-water radiators are fixed in front of fresh-air inlets at the floor level. The whole building and the grounds are lighted with electric light from the corporation mains, but gas is also laid on to all the rooms. A hydraulic lift is provided of sufficient capacity to enable a patient on a stretcher and an attendant to be taken from one floor to another and a double household lift is fixed in the administrative building. There is telephonic communication between all departments of the institution. In each bathroom there is an electric bell push, and upon being pressed a bell rings continuously until some person pulls a cord hanging immediately outside the bathroom door. This is an addition to the mechanism of electric bells which might well be placed in every public institution. The laundry, mortuary, and post-mortem room are in a one-storey building at the rear of the administrative block. The general arrangement of the hospital is admirably adapted for economical working and a great deal of care appears to have been bestowed upon matters of detail the first cost of which has no doubt been great, but it will be found in the end that the expenditure has been fully justified.

Sanitary Inspectors' Association.

The annual meeting of the Western branch of this Association was held on July 27th at Plymouth, Mr F M Williams, medical officer of health, presiding. Mr Victor Prigg read an interesting paper on the main drainage scheme now being carried out by the Corporation of Plymouth. Mr F M Williams, in replying to a vote of thanks for presiding, remarked that sanitary inspectors should be granted superannuation allowances in the same manner as Poor-law officers. Mr C Seale Hayne, M P, was re-elected president.

August 5th.

SCOTLAND

(FROM OUR OWN CORRESPONDENTS.)

University of Glasgow.

THE July graduation was, as is usually the case, mainly concerned with the "capping" of graduates from the medical faculty. The honorary degree of LL.D. was conferred on Dr James Dunsmure, President of the Royal College of Surgeons of Edinburgh, and on Mr W Mitchell Ramsay, M A, D C L, Professor of Humanity in the University of Aberdeen. Nine gentlemen received the M D degree and there were five successful candidates for the titles M B and C M. The present day degrees of M B and Ch B were conferred on 71 gentlemen and six ladies. Mr Alexander Dery Thompson and Mr W Macalister Brown graduated with "Honours," the former gaining the Brunton memorial prize as the most distinguished graduate of the year, and nine of the graduates were awarded "commendation." After the degrees had been conferred and the class prizes and distinctions announced an address was delivered by Sir Hector C Cameron, Professor of Clinical Surgery. The Senate have appointed Professor Ferguson, Professor Bower, and Professor R M Wenley to represent the University at the celebration of the bi-centenary of the Yale University, U S A, to be held in October next.

The late Mr John Ure, LL.D.

The announcement of the death of Mr John Ure intimates the removal from the civic life of Glasgow of one who in his day and generation rendered yeoman service to the cause of sanitary improvement in his native city. His first entrance on public life dates as far back as the year 1856 when he became a member of the town council and from that date until quite recently he has been more or less concerned with public affairs. The record of the offices to which he was elected by the votes of his fellow townsmen would itself be a lengthy list, and the secure position which his ability, honesty of purpose, courtesy and sense of duty had gained for him in the public confidence and esteem cannot be defined here. It is as a sanitary reformer and administrator that the memory of Mr Ure claims the sympathetic regard of the medical profession. It was early in the 'fifties, after the third invasion of cholera, that he began to display a strong interest in public health questions and the recognition of this led to his appointment as chairman of a committee on nuisances constituted by the town council in 1857. It was one of his early acts to secure the appointment of Dr (now Sir William) Gairdner as the first medical officer of health and it was the combined action of the chairman and the medical officer which swept away the old insanitary tenements and laid the foundation of the present elaborate public health organisation. The cleansing department was put into working order, foul fever dens were demolished, inquiries regarding drainage were instituted and last but not least a public opinion was created and organised. Mr Ure continued for many years to be the active champion of sanitary progress and was an important force in securing the passing of the City Improvement Act under the operation of which substantial workmen's dwellings now occupy the sites previously occupied by foul "lands" and "closes" opposed alike to health and morals. In recognition of his services to sanitation Mr Ure was in 1879 elected a Fellow of the Sanitary Institute of Great Britain, the University conferred on him the honorary degree of LL D and at the expiry of his term of office as Lord Provost of the City he was offered the honour of knighthood which, however, he respectfully declined. In his death there closes a long, generous and honourable career of service rendered for the public good.

University of St Andrews.

At the July meeting of the University Court the plans, specifications, and estimates for the erection of the new conjoint medical school at Dundee were approved and the committee in charge of this matter were authorised to proceed with the building. It was agreed that the installation of the Right Hon Lord Balfour of Burleigh as Chancellor of the University should take place in October. Dr James Musgrove, the lecturer in Anatomy in the University, was elected as first occupant of the Bute chair of anatomy. The followin
were made Dr A M
J Rorie on Mental Dise
Medicine, Dr James Greig, on Clinical Surgery, Dr G Taylor Guild on Diseases of the Throat, Nose, and Ear, and Dr R C Buist on Clinical Midwifery and Gynæcology. The elections to examinerships included Dr A Macphail (Glasgow) in Anatomy, Dr R B Ness (Glasgow) in Materia Medica, Dr D A Welsh (Edinburgh) in Pathology, Dr W J [illegible] (Edinburgh) in Forensic Medicine and Public Health, Dr R Kennedy (Glasgow) in Surgery, Dr W Russell (Edinburgh) in Medicine, and Dr W Fordyce (Edinburgh) in Midwifery. It is announced that Professor W S McCormick of University College, Dundee, has been elected secretary to the Carnegie Trust.

Glasgow Royal Infirmary.

Dr T K Monro, one of the physicians to the Infirmary, has been elected Professor of Medicine in St Mungo's College. Dr G Ritchie Thomson, who has for some months been on service in South Africa, has resigned his position as assistant surgeon, and Dr John Patrick has been elected as his successor.

Morningfield Hospital, Aberdeen.

At the last meeting of the acting committee of the Morningfield Hospital for Incurables, Aberdeen, it was reported that there being 80 patients in the institution there was at present no room for any more. It was agreed to carry out, according to a plan by Mr W Kelly, architect, of Aberdeen, certain alterations and additions to the buildings, including a new dining hall for the patients, the enlargement of the wash-house and laundry, kitchen, scullery, and larder accommodation, the erection of a private room for the medical officer, and additional bathroom and lavatory accommodation.

August 6th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Army Medical Service Committee.

A LETTER from Sir Thornley Stoker appeared in the *Times* of July 16th calling attention to the absence of Irish representation from the committee appointed to consider the state of the Army Medical Department. On July 18th in the House of Commons Mr. Balfour stated, in reply to Mr. Healy, that Sir William Thomson, C.B., of Dublin, had been asked to join the committee representing Irish schools of medicine. Sir Thornley Stoker has again addressed a letter to the *Times* on the subject, in which he complains that the representation is even now insufficient when it is remembered that in 1893 nearly half of the medical officers of the naval and military services of the Crown held Irish diplomas. The fact that the number has fallen now to 37 per cent., as stated by Mr. Brodrick, shows that young medical men from the Irish schools are more than dissatisfied with the prospects afforded by the service at present.

The British Pharmaceutical Conference.

The opening meeting of the British Pharmaceutical Conference was held in the lecture theatre of the Royal Dublin Society at Trinster House on July 30th, Mr. Druce, M.A., President of the Conference, being in the chair. The inaugural address was delivered by the chairman and it dealt with the present position of the science of pharmacy. The members were afterwards entertained at luncheon in the Mansion House. On the previous evening a reception was held at the Science and Art Museum, Kildare-street, at which the President was present with some 200 guests. The Conference terminated on August 2nd.

The Epidemic of Typhoid Fever in Belfast.

At a meeting of the City Corporation of Belfast held on August 1st an animated discussion took place on the deplorable state of affairs which was consequent upon the continued and increasing prevalence of typhoid fever in the city. During the period between June 16th and July 20th out of a total of 765 cases of zymotic diseases which were notified 505 were those of typhoid fever, the others being 168 of simple autumn fever, 30 of erysipelas, 29 of scarlet fever, 21 of diphtheria, 11 of croup, and one of typhus fever. The worst feature of the present outbreak of typhoid fever is that now it is prevalent in all the districts of Belfast, in the north, east, and west parts of the city and on both sides of the river. There were 167 deaths from zymotic diseases. Again, at the present time a serious outbreak of measles is present in Belfast of an unusually fatal type, having caused 55 deaths, and to crown all there were 133 deaths from phthisis and 104 from diseases of the respiratory organs. Further, while such figures are serious enough they are much more suggestively alarming when it is borne in mind that in the corresponding period of last year the deaths from zymotic diseases were 36, those from phthisis 112, and those from diseases of the respiratory organs 91, making a total of 203 from chest affections. The state of affairs as disclosed in the report of the medical officer of health of Belfast presented to the city corporation clearly indicates that a very full and exhaustive independent inquiry is needed as to these recurring epidemics of typhoid fever, which, apart from the terrible results to the inhabitants themselves, are doing the city so much injury abroad. Alderman the Right Hon. W. J. Pirrie, D.L., made the very practical suggestion that all personalities and fights between members of the corporation and officials should be set aside and that they should do their best to remedy the important matter before them. If they all tried to follow in the footsteps of those who had made Hamburg clear of the disease (and it was a difficult place to make right) they might be able to avoid the increase of typhoid fever. He advised the chairman to get information as to what had been done in that city. It is said that the Water Commissioners will shortly issue a counter report to the one recently brought out at the instance of the Public Health Committee which suggested the water as being the cause of the present outbreak of typhoid fever.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Contagiousness of Alopecia Areata.

THE Academy of Medicine has devoted much time to the consideration of this question, which is an ever-recurring subject of discussion. In a communication read by M. Jacquet a good while ago the opinion was expressed that alopecia areata was not a contagious disease and was not produced by a parasite, but was a trophoneurosis dependent on disordered nutrition, in proof of which the existence of a change in the proportions of the saline constituents of the urine was relied on. On the occasion of the presenting of a communication by M. Dezautière (Le Creusot), M. Hallopeau in his turn read a report in which he showed that of the arguments against the contagiousness of this disease not one possessed any real value, and that, on the other hand, proofs of its transmissibility were plentiful. There were numerous instances quite indisputable of small epidemics of alopecia areata in houses, in villages, in barracks, and elsewhere. The occurrence of epidemics in schools was equally well established; an additional example has been supplied by one observed by M. Dezautière in a school at Le Creusot, where two children who came from Paris suffering from alopecia areata infected successively several of their school-fellows, the teacher, and the children of another school. Moreover, there was no doubt that the clinical phenomena presented by alopecia areata were those of a parasitic disease progressing by successive auto-inoculations. Nevertheless, as the parasite has not yet been identified, and as it was certain that the disease was not transmitted by infection at a distance, being scarcely propagated except by direct contact, it was quite wrong, according to M. Hallopeau, to exclude the victims of this complaint from schools and offices; all that was required was that they should be careful to keep their heads covered, and it would be reasonable to amend the hygienic regulations in this respect. M. Du Castel was of opinion that alopecia areata was much less contagious than was formerly supposed, and it even appeared that there were varieties of it devoid of any contagious quality; but notwithstanding this it was the fact that no sufferers from the disease were allowed to remain in administrative offices, in workrooms, in shops, or in schools. It was desirable, however that less severe measures should be taken with respect to these persons and that they should not be treated as pariahs. M. Chauvel said that in the army there was no doubt about the infectiousness of the disease, regard being had to the numerous epidemics which make their appearance after a man suffering from it has joined. Beyond a doubt there were forms of it which were not contagious, but since no means of distinguishing them have as yet been discovered it was right in all cases to take precautions against the possibility of transmission. M. Fournier believed that it might be positively stated that in the great majority of cases the disease was not contagious; he regarded the measures taken against it as being far too severe, and he compared it with leprosy which, under some circumstances, was not found to be transmitted to those with whom the leper came in contact. It was also necessary to recognise that in addition to true alopecia areata, which was perhaps contagious, there were quite a number of pseudo-alopeciæ (in French "pseudo-pelades") or peladoid conditions which were not alopecia areata at all, particularly those which depended on syphilis. M. Fournier, therefore, agreed with M. Du Castel in thinking that the prospects of young persons suffering from alopecia areata ought no longer to be endangered, as happened too often, by excluding them from schools and colleges.

Actions-at-law brought against Medical Men.

The French law courts habitually treat medical men with extraordinary harshness, examples of which tendency I have frequently had occasion to mention in THE LANCET. Cases of this kind have been increasing for some time past, and the injustice of judgments which have been delivered have at last come to be bewildering; it appears as if the judges were actuated by a positive animosity against medical men and were endeavouring to increase the difficulties of practising a profession the conditions of which become worse every day. Recently a medical man attached to the dental clinic of the Hospital for the Blind requiring cocaine for a small operation on a patient sent a ward attendant to get some from the hospital dispensary The bottle brought back by the attendant was labeled "Chlorhydrate de Cocaine" but after the operation the patient suffered from severe sloughing and from necrosis of the jaw, for the bottle contained corrosive sublimate. The patient brought an action against the medical man and the courts held that the latter was responsible, as he argued that he could not analyse the contents of the bottle before the operation, that the bottle came from the dispensary with a label in due form and that such an interpretation of the law would make it impossible for any medical man ever to perform a surgical operation the judgment stated that the medical man had a simple way of avoiding the mistake—namely by going to the dispensary for the drug himself One is lost in astonishment at such decisions the effect of which is far reaching because the public begin to perceive that in taking legal proceedings [illegible] advantage and [illegible] or instance not [illegible] a young man [illegible] and as he was returning home accompanied by her she asked him what was the nature of her son in law's illness Having replied that it was tuberculosis he was subsequently proceeded against by the patient and compelled to pay a heavy penalty A patient who had been treated in hospital for a fracture of the leg is now bringing an action against the surgeon on the plea that the usefulness of his leg has not been fully regained.

BERLIN

(FROM OUR OWN CORRESPONDENT)

Female Medical Students in Germany

A RECENT number of the *Deutsche Medicinische Wochenschrift* contains some interesting statistics of the female medical students at present attending the German universities As I have mentioned on a former occasion[1] the Government is very favourably disposed towards medical study by women A few years ago there were no female medical students in German universities and German women desiring to become qualified as medical practitioners had to go abroad especially to Switzerland where no distinction was made in the conditions of study on the ground of sex The principal obstacle to women studying medicine in Germany was first that the entrance examination (Abiturienten examen) was not open to them because there were no "gymnasia" where females could receive training in classics mathematics &c Moreover, even if they had been admitted to the universities it was of little use for them to study because they were not allowed to pass the medical examinations necessary for qualified practitioners in Germany Matters have now been altered by the institution of gymnasia for the female sex and by a decree of the Federal Council allowing female medical students to present themselves for the State examination even though they may have taken part of their curriculum at foreign universities The official representatives of the profession constituting the medical chambers disapproved of the admission to medical practice both of women and of male students who had not been educated at gymnasia because they feared that the accession of these new classes of students would cause overcrowding in the profession The statistics of female students however, which have been collected by Professor Eulenburg show that female medical students have not come forward in such numbers as had been anticipated According to information supplied by all the German universities that of Munich only excepted where no particulars were obtained the total number of female medical students was only 95 of whom 56 were foreigners and 39 were Germans The greatest number were found in Berlin—namely, 25 of whom 21 were foreigners Next on the list came Leipsic with 24 of whom 22 were foreigners, then came Freiburg with 18 (including 14 foreigners) Halle with 12 (including nine foreigners) Heidelberg with six Bonn with five Breslau with two Strasburg with two and Konigsberg with one at the last mentioned five universities none of the female students were foreigners The preponderance of the foreign element among the female students is easily explained by the fact that foreign ladies when not wishing to undergo the State examination are admitted to attend the lectures without passing the entrance examination Many of the German universities have no female medical students at all—for instance Erlangen Giessen Göttingen Greifswald Jena, Kiel Marburg Rostock, Tübingen and Würzburg It is interesting to compare the number of the female medical students in Germany with those attending some of the Swiss universities Berne University has no less than 188 (of whom one is a German and 180 are Russians) Lausanne University has 61 and Zürich University has 85 (of whom 12 are Germans) so that Switzerland is evidently well patronised by female students The net result is that the total number of female German medical students is 52 of whom 39 attend German and 13 attend Swiss universities The increase of future medical practitioners of the female sex when compared with the number of the medical profession in Germany (amounting to 27 374) will therefore not be exceedingly great and Professor Eulenburg rightly observes that owing to the small number of medical women the representatives of the profession ought not to show any unfriendliness towards them

Professor Virchow on the Bacteriology of Tuberculosis

The Berlin Medical Society met for the last time before the summer holidays on July 25th Professor Virchow being in the chair The proceedings were not of general interest and the attendance was very small as the majority of the members had already left Berlin At the end of the meeting Professor Virchow instead of delivering the usual valedictory address alluded to the recently enunciated views of Professor Koch as to the non identity of tuberculosis in cattle with that affecting the human subject In his sarcastic style he remarked that he was happy to find that Professor Koch's views had undergone a change and were now in accordance with his own, for he had maintained that the mere presence of the Koch bacillus was not the essential thing in tuberculosis, a tubercle was in his opinion a growth with a distinct anatomical structure, and he had always protested against the bacteriologists terming *anything a tubercle simply because a Koch bacillus happened* to be present He said that the adherents to Koch's theory had believed his view to be rather old fashioned but it did not annoy him to recall to mind that he had sometimes been superciliously treated by the younger bacteriologists Professor Virchow's ironical words produced a great impression *on the meeting*

July 29th

Obituary.

JOHN SAMUEL SLATER M R C S Eng , L S A J P ,

MAYOR OF EVESHAM

THE death is announced on July 25th of Mr J S Slater which took place at the comparatively early age of 54 years after an illness of *only three days duration* He received his medical education at St Thomas's Hospital where he obtained the gold medal in general distinction and was resident obstetric physician He settled in Evesham in 1872 and on the retirement of the late Mr Anthony Martin from practice due to illness about that time he joined his son Mr A H Martin in partnership and with him he carried on a wide and extensive practice He was elected a member of the Evesham Town Council in 1879 and last November he was chosen mayor of the borough an office which he filled with great distinction so much so that the appointment met with the warmest approval from all sections of the community In a most eventful year he was always ready to carry out the duties devolving upon him among these may be mentioned those connected with the death of Her late Majesty the Queen the proclamation of the King the reception of the Gloucestershire and Worcestershire Agricultural Society in the town in June on the occasion of the annual show which lasted for three days and also the reception of the local volunteers from South Africa About five years ago he was placed on the Commission of the Peace for the borough and was very conscientious in the discharge of his magisterial work. Mr Slater was a man of high principle and honour and was greatly esteemed by all those with whom he came into contact in the exercise of his profession. He was attacked with acute gastro-enteritis on July 22nd, upon which heart failure supervened. The funeral was of a public nature and references were made to the sad occurrence in all the places of worship in the town. Mr. Slater was twice married and is survived by his widow, one son, and four daughters.

---

[1] THE LANCET Sept 8th 1900 p [illegible]

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Yersiloff, *privat-docent* of Neurology in Moscow.—Professor Karl Langenbuch, surgeon-in-chief to the Lazarus Hospital, Berlin.—Dr. Delpeuch of Paris.—Dr. Marston, a New York orthopædic surgeon.—Dr. Salishcheff, Professor of Surgery in the University of Tomsk.—Dr. Viertel of Breslau, a well-known surgeon whose speciality was diseases of the urinary organs.

Medical News.

VICTORIA UNIVERSITY.—In the Faculty of Medicine the following candidates at examinations held in July were successful:—

FINAL EXAMINATION.

Part I.—Roy Appleton and H. M. Birkett, Yorkshire; Walter Briggs and G. H. Brown, Owens; A. E. Burkhard, Yorkshire; A. G. Christian and J. A. Davenport, Owens; R. T. Dobson, University; J. E. Floyd, W. P. Grant, and P. T. Harding, Owens; J. L. Hawkes and H. E. Heapy, University; James Hindshaw, G. R. Hitchin, Alexander Hodgkinson, C. H. H. Hopwood, Arthur Howard, J. R. Hutchinson, H. L. Jenkins, S. J. C. Johnson, and J. A. Jones, Owens; G. W. N. Joseph, University; R. G. Ladell, Yorkshire; A. W. Latham and G. H. Leigh, Owens; J. A. Longley, Yorkshire; Joseph Longworth, Owens; Percival Pollard, Yorkshire; Arthur Richmond, C. A. Ricketts, W. E. Rothwell, J. A. C. Roy, S. H. Ryan, F. W. Scholield, W. F. Shaw, and A. F. Thompson, Owens; Ernest Tinker, Yorkshire; A. E. Townley and F. E. Tylecote, Owens; G. F. C. Walker, University; and T. B. Wolstenholme, M. S. Wood, and W. S. Wrigley, Owens.

Part II.—D. M. Alexander and E. L. Anderson, University; M. B. Arnold, Owens; Herbert Bates, University; A. D. Beckett, Owens; J. L. Beldoes, University; S. B. Brentnall and H. N. Bridge, Owens; Henry Brown, Yorkshire; E. R. Cooper,† J. F. Corson, J. M. Cort, and E. N. Cunliffe,* Owens; S. W. Davies, University; D. J. Ferris, Owens; A. H. B. Fletcher, Yorkshire; F. S. Fletcher, Owens; J. A. C. Forsyth, Yorkshire; Mercier Gamble† and Walter Garstand, Owens; G. W. Gelderd† and V. J. Glover, University; P. H. Green† and J. W. Greenwood, Owens; F. Griffith, University; F. W. Harrowell, Yorkshire; Walter Hickey and W. C. Johnson, Owens; R. J. Jones and R. E. Kelly,† University; James Kemp and Charles Mackey,† Owens; J. C. Mann, University; S. B. Mehta and A. H. Priestley, Owens; T. F. Pugh, University; P. A. H. Radcliffe, Yorkshire; H. H. Rayner, Owens; E. C. Roberts, University; F. M. Rodgers and F. R. Sawdon, Owens; Edwin Saville,† Yorkshire; G. H. Shaw, W. R. N. Smithard, and J. H. Stephens, Owens; W. A. Stott and J. H. Sutcliffe,† Yorkshire; H. G. Tansley,† Owens; A. R. Thompson, Yorkshire; Harold Thorp, R. N. West, H. W. Whiteley, T. B. Williams, and B. M. Wilson, Owens; F. P. Wilson, University; and W. J. Woodyatt and J. G. Woolham, Owens.

* Awarded first-class honours. † Awarded second-class honours.

SECOND EXAMINATION.

A. Anatomy and Physiology.—R. A. H. Atkinson, Owens; J. A. M. Bligh, University; F. L. Boag, Owens; Neville Bradley, University; Archibald Cambell, J. B. Dalton, J. A. Davies, J. P. Garlick, Marshall Hooper, W. H. Judson, F. H. Lacey, A. S. McNeil, W. Y. Martin, Stuart Murray, and C. S. O'Neill, Owens; W. V. Pegler and E. W. Reed, Yorkshire; G. H. H. Russell, Owens; Henry Woods, University; and A. R. Wright and William Wright, Owens.

B. Materia Medica and Pharmacy.—Fred Bailey and F. P. H. Birtwistle, Yorkshire; J. A. Blig [illegible] Boag, Owens; J. L. Brown, University; [illegible] therine Chisholm, Catherine L. Corbett, [illegible] J. B. Dalton, G. D. Dawson, H. S. Dixon, R. L. Ferguson, and W. G. Fuller, Owens; F. W. M. Greaves, Yorkshire; A. E. Grisewood and W. L. Hawksley, University; W. H. Hey, Owens; Pantland Hick, University; E. E. Hughes and Ernest Hulmes, Owens; G. H Joseph and G. J. Keane, University; Lawrence Kilroe, E. C. Lea, and Hector Mackenzie, Owens; James McClellan, University; H. J. Macvean, Yorkshire; W. Y. Martin, Owens; R. H. Mole and L. D. Napier, University; R. K. Porter, Owens; R. B. Radcliffe, Yorkshire; F. G. Ralphs, Owens; J. S. Rowlands, University; G. H. H. Russell, Owens; G. C. Scott, University; J. F. Smith, Owens; J. N. M. Sykes, University; Philip Talbot, F. P. S. Thomas, and Leonard Thorp, Owens; Herbert Tomlin, Yorkshire; T. E. Walker, University; T. W. Walker, Owens; H. W. L. Waller, University; F. J. Walton, Jerry Whitehead, and W. D. Wilkins, Owens.

DIPLOMA IN PUBLIC HEALTH.

W. S. Sinclair, W. H. Waddington, M.B., J. W. Wells, and R. H. Wilshaw, M.B.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS OF EDINBURGH AND FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—At the July sittings of the Scottish Conjoint Board held in Glasgow the following candidates passed the respective examinations:—

First Examination—William Noble Walker, James Taylor (with dis- [illegible] Alfred
tinction), James Alfred A [illegible] hool,
Edwin M'Dougal, all of [illegible] llege,
Glasg [illegible] and
Glasg [illegible] er, and Daniel
Willia [illegible]
Thom [illegible] rshall Metcalfe,
Second [illegible]
Ander [illegible] Miller Ramsay,
Second examination, five years course. [illegible] Thomas M'Master Glen,
David Haig, James Booth-Patterson, Thomas M'Master Glen,
and Alexander Glen, all of St. Mungo's College; William Arthur
[illegible] both of Queen's College, Cork; Patrick
Magill [illegible] y; and Cecil James Todd,
Franci [illegible] castle.
Durha [illegible] Thomas Longmore Ashford,
Third ex [illegible]
Anderson's College Medical School; Alexander Russell Young,
Robert Calder Blyth, David Roberts Williams, and Thomas Weir
[illegible] College, Glasgow; David Christie and
M'Cubbin [illegible] d St. Mungo's
R. Vithal [illegible] e University,
College, [illegible] Cork; Grace
Dublin; [illegible] lon School of
Eleanor [illegible] een's College,
Medicine [illegible]
Belfast; Frederick Herbert Maberly, Mason College, Birmingham;
and Arthur G. Jackson [illegible] co-operating
Final Examination (and [illegible] Noble, Oliver
authorities).—John M [illegible] w, John Bell
Scanlan, Robert Ward [illegible]
Walker, and John Kean, all of St. Mungo's College; Marion Ethel
Unwin and Clara [illegible] School of Medicine for
Women; Sydney P [illegible] and William Alexander
Reid, all of Melbo [illegible] Cooper, Durham Uni-
versity Medical Sc [illegible] ity College, Liverpool;
Archibald MacMillan, Anderson's College Medical School (with
honours); Joseph Dalby Andrews, Yorkshire College of Medicine;
and Henry Christian Ernest Quin, Queen's College, Cork.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berne:* Dr. von Zehender, formerly Professor of Ophthalmology in Rostock, has presented his library to the University of Berne.—*Breslau:* Dr. Roland Sticher has been recognised as *privat-docent* of Midwifery and Gynæcology.—*Erlangen:* Dr. Ernst Graser has been offered the chair of Surgery. Dr. Aichel has been recognised as *privat-docent* of Gynæcology.—*Helsingfors:* The Czar has granted the petition of the Senate in favour of the adm[illegible] of female students to the University. —*Jena:* Dr. Seidel [illegible] of Pharmacology, the lectures in which subject will for the present be given by Professor Stintzing. Dr. J. A. Grober of Berlin has been recognised as *privat-docent* of Internal Medicine.—*Moscow:* Dr. Gulevich of Kharkoff has been appointed Extraordinary Professor of Medical Chemistry; Dr. Karusin has been appointed Professor of Descriptive Anatomy.—*Odessa:* Dr. Medviedeff has been appointed Extraordinary Professor of Physiological Chemistry.—*Paris:* Dr. Landouzy has exchanged his chair of Therapeutics for that of Clinical Medicine.—*Strasburg:* Dr. F. Weidenreich has been recognised as *privat-docent* of Anatomy and Comparative Anatomy.—*Tübingen:* Dr. Albert Dietrich has been recognised as *privat-docent* of Pathological Anatomy.—*Vienna:* Dr. von Widerhofer is resigning his chair of Children's Diseases which has been offered to Dr. Escherich of Gratz. Dr. R. Kraus has been recognised as *privat-docent* of General and Experimental Pathology.

PRESENTATIONS TO MEDICAL PRACTITIONERS.—After the distribution of the certificates and prizes to the St. John Ambulance Association first aid classes held at Assuan, Upper Egypt, among the Englishmen employed at the Great Dam Works by Messrs. John Aird and Co. and the Egyptian Government, Mr. A. T. White, the chief surgeon to Messrs. Aird's Hospital and to the Government, was presented by the members of the class with a carved "Mushrabieh" screen and a case of pipes and gold and amber cigar and cigarette tubes in token of their regard and in appreciation of his services as lecturer to the class. Of this class of 17 members 14 qualified for the certificate of the association and it is the first class held by the association in Egypt. At Assuan, where accidents are so common and so severe, the members have done good work in rendering first aid to those injured by blasting and through accidents with machinery and also to the many cases of heat apoplexy which are bound to occur where Europeans have to work in a heat which has registered not infrequently 122° F. in the shade, and where it is constantly in the daytime from 110° to 112°.—On July 26th, at 41, Belsize-park, Dr. Ford Anderson presented Dr. Edmund Gwynn, on behalf of the *medical practitioners of the neighbourhood, with a pair of* silver candelabra and a silver bowl, together with a handsomely bound album with 60 signatures, on the occasion of his retirement from the post of medical officer of health of Hampstead; and on July 24th, at the Hampstead Town Hall, Professor Stokes presented Dr. Gwynn with a set of four silver bowls on behalf of his colleagues on the Hampstead borough council.—*After the meeting of the Epsom Board of Guardians* held on July 31st, Mr. E. B. Jay, on behalf of past and present members of the Epsom Urban and Rural District Councils and Board of Guardians, presented a silver tray and an illuminated address to Mr. Edward L. Jacob, M.R.C.S. Eng., L.S.A., who has been medical officer of health of the above-mentioned districts for upwards of 27 years.

APOTHECARIES' HALL, IRELAND.—At the annual meeting of the General Council of the Apothecaries' Hall of Ireland convened by the Act of Incorporation, 1791, on August 1st, the following were duly balloted for and elected to hold office for the ensuing year ending July 31st, 1902:—Governor: Mr. George A. Stritch. Deputy-Governor: Dr. Arthur Atock. Directors: Mr. Hugh A. Auchinleck, Mr. John Evans, Mr. William V. Furlong, Dr. J. Adam Johns, Dr. Thomas D. Finucane, Dr. Edward Hanrahan, Mr. Robert Montgomery, Mr. Robert J. Montgomery, Dr. Richard G. O'Flaherty, Mr. James Raverty, Mr. Joseph A. Ryan, Mr. James Shaw, and Mr. Charles R. C. Tichborne. Representative on the General Medical Council: Mr. Charles R. C. Tichborne. Secretary: Mr. Robert Montgomery.

LITERARY INTELLIGENCE.—In order to bring the late Dr. Norman Kerr's valuable and exhaustive work on Inebriety within the reach of the increasing number of those interested in the study of the subject the price of the enlarged third edition has been reduced to 7*s.* 6*d.* net. Mr. H. K. Lewis is the publisher.

Parliamentary Intelligence.

HOUSE OF COMMONS.

FRIDAY, AUGUST 2ND.

Medical Examination for the South African Constabulary.

MR. MUNRO FERGUSON asked the Secretary of State for the Colonies whether his attention had been called to the fact that Scottish candidates for the South African Constabulary had to proceed to London for [illegible] at the London recruiting office, as, apart from the medical examination, it is necessary that they should be seen by the constabulary re[illegible] I have sanctioned the grant of [illegible] Africa to selected candidates [illegible] expense to which they have been put. No difficulty is experienced in obtaining an ample supply of suitable candidates under the present conditions of recruiting, and so far, I believe, only one actual complaint has been received from Scotland.

The Improvement of Barracks.

Lord STANLEY announced that the War Office had decided to ask Parliament for money for the extension and improvement of many of the barracks in various parts of the United Kingdom.

Burgh Sewerage, Drainage, and Water-supply (Scotland) Bill.

This measure was read a second time and referred to the Grand Committee on Law.

MONDAY, AUGUST 5TH.

The Home Office and Lead-poisoning.

At this sitting of the House, on the vote for the salaries and expenses of the Home Office, several Members, including *Sir* CHARLES DILKE, Mr. TENNANT, and Mr. JOHN BURNS, called attention to the question of lead-poisoning in various industries and the action of the Home Office in this connexion.—Mr. RITCHIE, in the course of his reply, said that it was matter for congratulation all round to find that the number of lead-poisoning cases in 1900 had considerably decreased, and that the cases of phosphorus poisoning had disappeared. Complaint was made that the Home Office had been extremely slow with reference to the new rules. He assured Members that he had done his best to prevent delay in getting the question adjudicated, but negotiations were going on with the manufacturers at [illegible] nt was not without hope [illegible] arrived at. *If it had been* [illegible] with the manufacturers [illegible] postpone dealing with it [illegible] operation of arbitration. Looking at the condition of things at the beginning of the year, he came to the conclusion that, inasmuch as the law did not place on the Home Secretary the ultimate responsibility of deciding the question it was desirable to settle it by a *reference to arbitration. There had been some delay in* carrying the question to arbitration, but the two arbitrators had been decided upon and also the umpire. Lord James had undertaken at the request of the arbitrators to act as umpire, and although he could not promise any immediate decision he thought that members might rely upon it that no delay would be caused by Lord James if [illegible] allowed [illegible] trying [illegible] take [illegible] left [illegible] were convinced that there remained some room for improvement in the working of this dangerous material by which a still greater reduction could be made in the number of persons killed and permanently injured by this most desolating complaint it would have been most unwise on their part, and indefensible as well, to have allowed the question to rest where it was.

The Fees of Medical Witnesses.

Mr. [illegible] Home Office vote, raised the question of [illegible] attendance at police-courts and [illegible] which had never received adequate [illegible] on an Act of 1858. For a police-[illegible] for a medical witness was 10*s.* 6*d.* [illegible] n, for there were instances where [illegible] not the funds with which to make [illegible] sent to the assizes or the sessions the payment was a guinea for a day's attendance with an allowance if the witness had to remain in the town overnight. [illegible] nd refused £2 12*s.* 6*d.* [illegible] and two other long [illegible] fare. For such [illegible] and an [illegible] a couple [illegible]

[illegible] where they were celebrated for their economical administration, the fees given [illegible] those which appeared to be given in [illegible] the fees were fixed a good many yea[illegible] circumstances had in some degree changed. But while he did not dispute the fact that the amount of remuneration was small, it must be remembered that the *cost of prosecutions was great, and that they ought to be extremely* careful before they increased it unduly. Moreover, they could not take into account one class of witnesses merely, they must take into account the whole scale, and that was rather a formidable thing to undertake.

TUESDAY, AUGUST 6TH.

The Army Medical Department Report.

[illegible]

Questions about Tuberculosis.

Sir WALTER FOSTER asked the Secretary to the Treasury, as representing the Postmaster-General, whether his attention had been called to the conclusions of the British Congress on Tuberculosis, more [illegible] master-General has not received any authentic record of the conclusions of the British Congress on Tuberculosis, but he is considering what action it may be desirable for the department to take in regard to the matters referred to.—Mr. FIELD asked the President of the Local Government Board whether [illegible] respecting the admi[illegible] [illegible] o and report upon the [illegible] as intended to put a stop [illegible] that a decision had not at prese[illegible] to the matter referred to [illegible]

[illegible] asked the Chief Secretary to the Lord Lieutenant of Ireland, whether, in view of the pro[illegible] statements recently made by Professor Koch, to the effect that [illegible] tuberculosis of bovine animals was not transmissible, or but slightly so, to the human subject, and in view of the confiscations and trouble to which those engaged in the dairy and live-stock industries were being subjected in consequence of the assumption that the milk and meat of tuberculous animals were capable of conveying the disease to human beings, he would cause experiments to be carried out by the Local Government Board, in conjunction with the Department of Agriculture in Ireland, with the o[illegible] of setting finally at rest the question as to the transmissibility of bovine tuberculosis to the human race, and thereby either removing the restrictions alluded to or establishing their necessity.—Mr. Wyndham replied: This matter is engaging the attention of the two authorities mentioned in the question.—Mr. Field asked: Am I to understand that an inquiry of this nature will be made?—Mr. Wyndham answered: The two authorities are in conference and I do not know whether they have yet determined whether an inquiry is necessary.

Royal Irish Constabulary and First Aid.

Mr. Wyndham, in reply to a question, stated that all recruits in the Royal Irish Constabulary undergo a course of instruction in first aid treatment of the sick and wounded.

THE NEW FACTORY AND WORKSHOP LEGISLATION.

PROCEEDINGS IN THE GRAND COMMITTEE.

The Grand Committee of the House of Commons on Trade at its meeting on Thursday, July 25th, completed the consideration of the Bill of the Government to amend the Factory and Workshop Acts. Several subjects of special interest to medical men were discussed at this meeting.—Mr. Trevelyan moved the adoption of a new clause designed to prevent women in factories taking away work to do at home within four weeks of their confinement. The hon. Member called the attention of the committee to a report by Miss Deane, factory inspector, in which it was stated that a woman only a few days after her confinement was found washing at home for the laundry at which she was ordinarily employed. The law prevented her working in the laundry but allowed her to take work to her own home, where the conditions were much worse than in the laundry. This, he submitted, was a state of things which ought to be stopped.—Mr. Ritchie, however, opposed the clause. The effect of it, he said, would be to prevent women doing any work, no matter how light, for four weeks after their confinement. He agreed that women so circumstanced should not overwork themselves, but he thought it would be a great hardship upon many of them if they were prevented by law from doing any work at all, because it might seriously interfere with their means of livelihood. —The Committee negatived Mr. Trevelyan's proposal without a division.—A new clause, of which notice had been given by Mr. John Burns, saying that "after the first day of January, 1904, an underground kitchen of any hotel or restaurant shall not be used for the cooking or preparation of food for sale," was ruled out of order by the Chairman of the Committee.—Sir Fortescue Flannery moved to insert in the Bill a clause in these terms—viz.: "The Secretary of State for the Home Department may by order make regulations for the better investigation bacteriologically of anthrax disease."—The Chairman ruled the clause out of order as proposing something outside the scope of factory legislation.—Sir Fortescue Flannery pointed out that it dealt with a disease acquired only in factories, and Sir Charles Dilke reminded the Chairman that anthrax was specially named in connexion with other highly dangerous diseases in the Factory Act of 1895.—Mr. Ritchie said it was perfectly true that anthrax came within the purview of the Home Office, but this clause proposed to convert the Home Office into an investigating department for which it had no sort of equipment.—After some further debate, Sir Fortescue Flannery altered the form of his proposed clause, making it read, "The Secretary of State for the Home Department may, by order, make regulations as to the reporting by factory inspectors and surgeons of cases of anthrax disease," and the Chairman allowed him to move it in this form. The hon. Member explained that the employers and the employed who were concerned in this matter were agreed that there should be better facilities for the investigation of this terrible disease and they had adopted a form of rule. Medical opinion, however, had not approved that form of rule. Medical opinion was that regulations had better be left to the discretion of the Secretary of State, and now all three interests were in agreement that the Secretary of State should undertake this duty.—Mr. Ritchie said that if he did not accept this clause it was not because he disagreed with his hon. friend as to the seriousness of anthrax and the necessity for the Secretary of State taking adequate means to endeavour to deal with it, but it was because all the powers proposed were already in the hands of the Secretary of State. There was no need for regulations as to reporting by officers who were the servants of the Department. All the Secretary of State had to do was to give instructions to these officers and the thing would be done.—Mr. Louis Sinclair thought that if there were a statutory obligation to have these cases reported there would be a better chance of a proper inquiry.—Mr. John Burns said that he objected to any one disease being singled out for special treatment in an Act of Parliament.—Mr. Taylor said that this disease was specially obscure and specially dangerous and in his opinion it was worthy of, and required, special investigation.—Sir Charles Dilke said he thought that there was a grievance in connexion with this matter. A case had been made out, not against the present Home Secretary but against the Home Office, of not having done all that might have been done. But the matter was one of administration rather than legislation, and he thought an assurance from the right hon. gentleman would meet the case.—Mr. Ritchie, in response to this suggestion, said that the committee might rest assured that the Home Office were quite alive to the extreme gravity of this disease and to the responsibilities which rested upon them in connexion with it, and they might rely upon it that nothing would be wanting on his part to endeavour to deal successfully with it. Further, he would be glad to put himself in communication with the Local Government Board to see whether they had any suggestions to offer.—Sir Fortescue Flannery, accepting this assurance, withdrew his proposed clause.—Captain Jessel put forward a proposal to require the chief inspector of factories to send to the medical officer of health of the district a notice of cases of anthrax and certain other diseases, but the Home Secretary opposed it as involving unnecessary trouble upon the chief inspector of factories and it was not pressed.

The amending Bill which has been the subject of so much discussion before the Grand Committee and the Consolidating Bill have been embodied in a single measure of 153 clauses and seven schedules, and it is this measure which will be discussed in the House of Commons on the report stage. It embodies the whole of our factory and workshop legislation.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to The Lancet *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.*

Butler, William, M.B. Glasg., C.M., D.P.H., R.C.P.S. Lond., has been appointed Medical Superintendent, Isolation Hospital, Willesden, vice D. S. Skinner, M.D., resigned, and Assistant Medical Officer of Health to the Willesden Urban District Council.

Gough, J. H., F.R.C.S. Edin., L.R.C.P. Lond., has been appointed Certifying Surgeon under the Factory Acts for the Torquay District of Devonshire.

Haswell, W. C., M.B., B.S. Durh., has been appointed Certifying Surgeon under the Factory Acts for the Flaxton Rural District of the North Riding of York.

Macnair, Norman, B.S., M.D. Glasg., M.R.C.S. Eng., L.R.C.P. Lond., has been appointed Extra-Dispensing Physician to the Glasgow Royal Infirmary.

Patrick, R., M.D. Durh, M.R.C.S., L.R.C.P. Edin., has been appointed Certifying Surgeon under the Factory Acts for the South-east Bolton District.

Pearson, H. Carden, M.B., F.R.C.S. Edin., has been appointed Surgeon to the Darlington Hospital.

Turner, B. R., M.B., B.S. Camb., has been appointed Certifying Surgeon under the Factory Acts for the Oundle District of Northants.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

Birmingham City Asylum.—Senior Assistant Medical Officer, also Junior. Salaries respectively £180 and £130 per annum, with board, apartments, and washing.

Bradford Royal Infirmary.—Dispensary Surgeon, unmarried. Salary £100 per annum, with board and residence. Also Junior House Surgeon, unmarried. Salary £50 per annum, with board and residence.

Brecon Infirmary.—Resident House Surgeon, unmarried. Salary £100 per annum, with furnished apartments, board, and attendance.

Denbighshire Infirmary, Denbigh.—House Surgeon. Salary £100, with board, residence, and washing.

Devon County Asylum, Exminster.—Third Assistant Medical Officer. Salary commencing at £125 per annum, and increasing at the rate of £10 per annum to £155, with board, residence, &c.

Devonshire Hospital, Buxton, Derbyshire.—Assistant House Surgeon. Salary £50 per annum, with furnished apartments, board, and washing.

District Hospital, West Bromwich.—Resident Junior House Surgeon. Salary £50 per annum, with board, lodging, washing, and attendance.

Eastern Counties' Asylum for Idiots, Imbeciles, and the Feeble-minded, Colchester.—Resident Medical Attendant, unmarried. Salary £100 per annum, with furnished apartments, board, and washing.

East Suffolk and Ipswich Hospital.—Second House Surgeon, unmarried. Salary £80 per annum, with board, lodging, and washing.

Essex and Colchester Hospital.—House Surgeon. Salary £100 per annum, with board, washing, and residence.

Fulham Infirmary, St. Dunstan's-road, Hammersmith, W.—Locum Tenent for four weeks. £3 3s. per week, with board, apartments,

shing.

Leeds.—Assistant Resident Medical Officer f

at rate of £100 a year.

Hospital, Salterhebble.—Medical Officer.

Salary £100 per annum.

Hull Royal Infirmary.—Casualty Officer. Salary £60 per annum, with board and lodging.

Kent and Canterbury Hospital.—Assistant House Surgeon, unmarried. Salary £60 a year, with board and lodging.

Lewes Dispensary and Infirmary and Victoria Hospital.—Resident Medical Officer. Salary £100 per annum, with apartments, board, and attendance.

Liverpool Infirmary for Children, Myrtle-street.—Assistant House Surgeon for six months. Salary £25 for the six months, with board and lodging.

Manchester Royal Eye Hospital.—House Surgeon.

North London Hospital for Consumption, Hampstead.—Junior Resident Medical Officer for six months. Honorarium at rate of £60 per annum.

Nottingham General Dispensary.—Assistant Resident Surgeon, unmarried. Salary £160 per annum, increasing £10 every year, with furnished apartments, attendance, light, and fuel.

Owens College, Manchester.—Junior Demonstrator in Physiology. Salary £100, rising to £150 per annum.

Plymouth Borough Asylum.—Assistant Medical Officer, unmarried. Salary £150 per annum, rising to £200, with apartments, board, and washing.

Preston Royal Infirmary.—Assistant House Surgeon. Salary £60 per annum, with board, lodging, and washing.

Royal Boscombe and West Hants Hospital, Bournemouth.—House Surgeon. Salary £80 per annum, with board, lodging, and washing.

ROYAL LANCASTER INFIRMARY.—Assistant House Surgeon, single. Salary £60 a year, with residence, board, attendance, and washing.

ROYAL SOUTH HANTS AND SOUTHAMPTON HOSPITAL.—Junior House Surgeon for six months. Salary at rate of £50 per annum, with rooms, board, and washing. Also Dispenser. Salary £60 per annum, with board [illegible]

ROYAL [illegible] House Surgeon [illegible]

SALOP [illegible] ary £100 per ann[illegible]

STAFFO[illegible] [illegible]stant Medical Offi[illegible] ard, lodging, atte[illegible], and washing.

STAMFORD, RUTLAND, AND GENERAL INFIRMARY.—House Surgeon. Salary £100 per annum, with board, lodging, and washing.

SUSSEX COUNTY HOSPITAL.—[illegible]

TAUNTON AND SOMERSET [illegible] *House Surgeon.* Salary [illegible] lodging [illegible]

[illegible] ARY, Liverpool.—Resident [illegible] with board [illegible]

[illegible] lodging, and washing provided. Also Assistant House Physician. Honorarium at the rate of £75 per annum will be given. Board, lodging, and washing provided.

WOLVERHAMPTON EYE INFIRMARY.—House Surgeon. Terms, £70 per annum, rooms, board, and washing.

THE Chief Inspector of Factories, Home Office, London, S.W., gives notice of vacancies for Certifying Surgeons under the Factory Acts at Basingstoke and at Croydon.

Births, Marriages, and Deaths.

BIRTHS.

ALLEN.—On July 31st, at Hirzel House, Guernsey, the wife of James Davidson Colquhoun Allen, M.B. Edin., of a son.

BANNERMAN.—On July 29th, at High Wycombe, the wife of G. D. K. Bannerman, M.R.C.S., L.R.C.P. Lond., of a daughter.

COWAN.—On the 4th inst., the wife of Horatio Cowan, M.B., C.M., 32, Fitzroy-square, W., of a [illegible]

GEDDES.—On [illegible] wife of J[illegible]

GUNDLACH.—[illegible] N.I., the [illegible]

LONG.—On Ju[illegible] Frank Tho[illegible] of a daughter.

MUNDAY.—On July 30th, at the Royal Marine Infirmary [illegible]

OCT[illegible]

POR[illegible]

RUS[illegible] Crumpsall, Manchester, the wife of John Rust, M.R.C.S., L.R.C.P., of a son.

STABB.—On July 30th, at Harleston, Torquay, the wife of W. Wilking Stabb, M.D., of a [illegible]

SWALLOW[illegible] road, S.W., the w[illegible]

WHITE.—[illegible] the wife of Finch [illegible]

MARRIAGES.

CALVERLEY—DOUËT.—*On July 27th, at St. John's, S.E., Ernest Joseph* Goodfellow Calverley, M.B., B.S. Lond., M.R.C.S., L.R.C.P., of Claremont House, Folkestone, to Evelyn, daughter of L. Douët, Esq., of St. John's.

DARBYSHIRE—WORLEY.—On August 1st, at St. John's Church, Perth, W.A., by the Right Rev. the Bishop of Perth, Douglas Edward Darbyshire, M.B., L.R.C.P., M.R.C.S., second son of Edward *Darbyshire, of Norwood, late of Liverpool, to Florence, second* daughter of William Charles Worley, L.R.C.P., M.R.C.S., of Green lanes, N.

DONALD—LINNER.—On the 6th inst., at St. Paul's, Winlaton-on-Tyne, by Rev. Arthur Jones, M.A., rector, David Donald, L.R.C.P., L.R.C.S. Edinburgh, L.F.P. & S. Glasgow, to Bessie, daughter of the late Francis T. Linner, Newbiggin, Northumberland.

***HOWARD JONES—PEACOCK.**—At Brent, by the vicar, Rev. H. Speare* Cole, John Howard Jones, M.R.C.S. Eng., L.R.C.P. Lond., of Polyphant, Launceston, to Blanche Evelyn Gladys, youngest daughter of F. B. Peacock, late Indian Civil Service, and grand-daughter of the late Sir Barnes Peacock. Indian papers, please copy.

LYLE—SELF.—On July 31st, at Holy Trinity Church, Blackheath-hill, *by the Rev. E. F. Hooper, rector of Lydlinch, Dorset, assisted by* the Rev. R. Bayne, M.A., vicar, Herbert Willoughby Lyle, M.D. London, M.R.C.S., F.Z.S., elder son of Thomas Lyle, M.A., of the Board of Education, to Elizabeth Ada, the eldest daughter of James D. Self, of Blackheath Rise.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE DUTIES OF A MEDICAL OFFICER OF HEALTH AND HIS RESPONSIBILITIES.

AT the recent Warwick Assizes, before Mr. Justice Phillimore and a jury, Robert Clarke, a farmer, of Benhill, Atherstone, sued Robert Mears, M.R.C.S. Eng., L.R.C.P. Edin., medical officer of health of the Atherstone Rural District Council, *to recover damages* for slander. Counsel for the plaintiff put in a letter written by the defendant on April 21st, 1900, and containing the passage: "It has come to my knowledge that tuberculosis to a serious extent is prevalent among your cows. As medical officer of health and pending the meeting of the district council I must *warn you to discontinue the sale of milk until a veterinary certificate* of the freedom of your cattle from tuberculosis has been produced." Clarke gave evidence that he had acted upon the letter and discontinued the sale of milk, whereby he alleged that he suffered damage. He declared that tuberculosis had not existed among his cattle, and the gist of the action was to show that the defendant had not ascer*tained that his facts were accurate before he wrote the letter which* had caused the plaintiff pecuniary loss. The plaintiff in answer to the judge said that he took the letter to be a [illegible] council, wherefore he had acted [illegible] to be free from tuberculosis [illegible] they had bought cattle from the plaintiff which were not tuberculous, and one of these made th[illegible] ment that he had bou[illegible] perfectly healthy—they [illegible] Ison, a veterinary surgeon who had been called in to treat one of plaintiff's cows, said that he had made no examination of the cattle for tuberculosis, but that all the cattle were poor, especially two of them. A diagnosis of tuberculosis had been present in his mind, but he did not in words suggest that the cattle were so affected. The defendant gave evidence that he had heard from the son of the veterinary surgeon that his father considered that Clarke's cattle were tuberculous. Upon this information which he consid[illegible] [illegible] letter as an order unless he were conscious of the presence of tuberculosis. Various witnesses gave evidence as to the poor condition of Clarke's cows. Mr. Ison, jun., spoke of visiting the farm with his father when he saw two cows that he considered tuberculous and which he suggested should be destroyed. The jury agreed that the defendant reasonably believed that tuberculosis existed among the plaintiff's cows to a serious extent. This, said the judge, was equivalent to giving a verdict for the defendant, and judgment was given accordingly, with costs and certificate for a special jury.

On the evidence the jury could have come to no other conclusion. Numbers of witnesses, some of them being called for the plaintiff, deposed to the poor condition of the cows, and one witness actually said that he had bought dead cows from Clarke which, though perfectly healthy, had died from weakness. The younger veterinary surgeon, who had actually seen the cattle, believed that two at least were tuberculous, while a similar diagnosis was present to his father's mind. The defendant, it seems to us, was quite justified in writing as he did on such information. The future health of the neighbourhood is in his care. The infant mortality is high and is partly attributable to tuberculosis. He believed honestly *and on good primâ facie grounds that he had found a focus of the* disease and he took the only immediate step in his power to prevent its spread. We congratulate him upon the verdict which received a marked endorsement from the judge. The whole story, by the way, furnishes one more instance of how the duties of a medical officer of health bring him into conflict with his neighbours and *therefore one more argument for putting medical officers of health* into such a position that they will be independent of private practice.

AN OBNOXIOUS BUSINESS.

To the Editors of THE LANCET.

SIRS,—Permit me to call your attention to the recent method now being adopted in country towns and villages for the spread of disease and the dissemination of a most dangerous source of evil, thereby causing the pure country air to be polluted with obnoxious smells to the danger of the public health. The recent boom in the manufacture of bricks has caused a great many new brickfields to be opened for their manufacture, and where land could be obtained near a railway station brickyards on a large scale have been introduced in the locality through the facility of sidings. Railway companies are only too glad to encourage this branch of industry and are continually carrying truckloads of refuse from large towns to these new enterprises. The stench arising from this filth is simply abominable and may be noticed at the sidings of several railway-stations which could be named. This refuse is much cheaper to the brickmaker than screened ashes which were formerly used. Then there is the carting of the refuse through the roads and streets where houses are closely built. Even in this town, during hot weather especially, carts may be seen loaded with this filth covered on top with a bit of canvas to prevent the wind blowing it into the gardens as they pass along, and people may be seen with handkerchiefs to their noses as they pass the carts. Another objection is the burning of this filthy rubbish close to the dwelling-houses in the poorer districts—even within 100 yards of a large local school where about 300 children may be seen playing about. If this is to continue the spread of diphtheria, measles, and other complaints must soon be alarming, as the inhalation of such obnoxious smells must result in much illness. Surely immediate steps should be taken to stop this nuisance, and I trust that you will use your powerful influence in drawing the attention of medical men to the matter.

I am, Sirs, yours faithfully,

Horsham, July 31st, 1901. WILLIAM BUCK.

⁂ We sympathise with our correspondent in his hearty dislike to the smell of brick-manufacturing, but pathology does not bear out his apprehension of a spread of diphtheria or measles in the neighbourhood of brickfields.—ED. L.

WHITE PRECIPITATE IN INFANTILE DIARRHŒA.

To the Editors of THE LANCET.

SIRS,—Recently in attending at a coroner's court I heard the evidence of a medical man to the effect that he had prescribed for the subject of the inquiry—an infant, aged five months—a mixture of liq. hydrarg. perchlor. with aromatic spirit of ammonia. Unless my chemistry is at fault this combination would produce "white precipitate." It may be that my therapeutic knowledge is "behind the times" and that this is the most "up-to-date" agent in the treatment of infantile gastro-enteritis, but till now I believed hydrargyrum ammoniatum to be an irritant poison. Times change and methods of treatment with them and this may be a useful innovation. I should be glad to know if any of my professional brethren have experience of it.

I am, Sirs, yours faithfully,

August 5th, 1901. EDWIN T. ENSOR, M.D.

PUBLICITY.

WE have had our attention called by more than one correspondent to the following newspaper paragraphs during the week:—

> *Dr. and Mrs. Fenton have left 27, George-street, Hanover-square, for Recess, Connemara.* *Daily Telegraph*, August 2nd.
>
> Dr. T. Miller Maguire wishes it to be known that he will remain at 12, Earl's-court-square throughout the summer, and will be glad to see his clients daily from half-past 11 till half-past one o'clock, or by appointment at other hours. *Morning Post*, August 3rd.

Our correspondents seem to have thought that the two paragraphs were examples of advertisement by medical men of their private movements. With regard to the second paragraph our correspondents are completely in error. Dr. T. Miller Maguire is not a medical man, and the clients whom he is ready to see by appointment are not patients, but pupils who are being prepared for various examinations. The paragraph concerning Dr. Fenton's holiday arrangements is certainly not one which a medical man should seek to have inserted in the editorial columns of a newspaper. If the information has been published without Dr. Fenton's knowledge he should ask the editor of the *Daily Telegraph* to be more discreet in the future.

THE RE-MAKING OF MATTRESSES.

WE have received a letter which we print below on the subject of the necessity that woollen mattresses should be re-made at reasonable intervals. It is clear enough that the letter is from a layman, and there are sentences and sentiments in it with which we do not agree, but the communication as a whole is valuable. There is no doubt that in England the simple sanitary precaution of re-making the mattress is much neglected even by housekeepers whose care for the hygiene of their households is great and elaborate.

To the Editors of THE LANCET.

SIRS,—I have been greatly interested by the various reports of the proceedings of the Congress held last week in London for the cure of tuberculosis, and although the delegates have gone far in their debate as to preventive means, such as spitting in the streets, &c., yet to my idea they have not gone far enough. The English, though a clean nation, pay no attention to their bedding; they will sleep on their mattresses for years without thinking of having them re-made. As to what their mattresses are made of they are quite indifferent. I am an upholsterer and ignorant of what might be a hotbed for breeding bacilli; I leave that for the doctors to find out whether there is anything in my theory. I will give a few examples of my experience. A few years ago I had the order to make a very sumptuous carved bedstead—the curtains were of brocaded silk—but the lady did not wish me to re-make her bedding as she said it was very comfortable. I had to undo the side of the mattress and found that it was made of what is called "coloured wool." Now coloured wool, which is used largely for cheap bedding, is composed of old woollen rags, such as old clothes, carpets, &c., also the refuse sweepings of the floors, &c., of woollen factories. It goes through a machine called the "devil," but goodness knows whether Old Nick is charitable enough to eliminate the microbes. I argued with the lady but to no purpose. I had it on the tip of my tongue to repeat the rhyme of Margery Daw, but I thought better of it. The lady still sleeps night after night on the same mattress. Another case—a gentleman in the country. His daughter was suffering with a sore-throat. His medical man advised him to send for a specialist. Of course, he condemned the drainage, over which the gentleman spent over £1000. And yet to my knowledge not a single mattress has been re-made in the house for the last 20 years, and the servants' mattresses are a mass of corruption, and it is about the same all over England. The English housemaids do their work in a slovenly manner; the mattresses are hardly ever turned, and as for brushing and airing them that is quite out of the question. Now, what a difference with the French people. Take, for instance, the working-class. They do not lie on shoddy and muck; their bedding is of white wool or horsehair; and you can see in the Faubourgs of Paris, such as Belleville, Grenelles, Montmartre, &c., the bedding airing at the windows; besides which men come round to re-make the mattress, for in France the poorest person would never think of sleeping on a mattress which had not been re-made within two years.

I am, Sirs, yours faithfully,

July 29th, 1901. H. C. R. J.

We do not know if experts in domestic furniture would bear out our correspondent's statements that French bedding is so much superior in make to English bedding, but undoubtedly the French domestic servant is more thorough in her care of sleeping-rooms than is her English sister.

◆

Glasgow.—The matter is one of taste, not of rule, and must be left to our correspondent to decide for himself. The comparison of his institution, doubtless a useful private venture, to King's College, London, does not strike us as happy.

C. E. C.—The matter is one to which we have already called pointed attention. See, for example, an annotation in THE LANCET of Oct. 13th, 1900, page 1088.

Typhoid.—No British university and very few, if any, foreign universities, save the one our correspondent has named, hold out the required facilities.

Wirrimbirchip has not given us sufficient information to make it possible to reply.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff It is urgently necessary that attention be given to this notice

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers not necessarily for publication.

We cannot prescribe or recommend practitioners

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub Editor"

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager"*

We cannot undertake to return MSS not used

MANAGER'S NOTICES.

THE INDEX TO THE LANCET

THE Index to Vol I of 1901, which was completed with the issue of June 29th, and the Title page to the Volume, were given in THE LANCET of July 6th

VOLUMES AND CASES

VOLUMES for the first half of the year 1901 are now ready Bound in cloth, gilt lettered, price 18*s*, carriage extra.

Cases for binding the half year's numbers are now ready Cloth, gilt lettered, price 2*s*, by post 2*s* 3*d*

To be obtained on application to the Manager, accompanied by remittance

TO SUBSCRIBERS

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W C, are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c, should be sent to the Agent to whom the subscription is paid and *not* to THE LANCET Offices

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are —

FOR THE UNITED KINGDOM		TO THE COLONIES AND ABROAD	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance *Cheques and Post Office Orders (crossed* "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W C

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions Any demand for increased rates on this or any other ground should be resisted The Proprietors of THE LANCET have for many years paid, *and continue to pay*, the whole of the heavy cost of postage on overweight foreign issues, and agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied Address—THE MANAGER THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND

An original and novel feature of "The Lancet General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in The Lancet.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. Charles Good, The Lancet Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

The Lancet can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 8, Rue Traversière, Asnières, Paris.

Remarks

ON

THE DIAGNOSIS AND SURGICAL TREATMENT OF CARCINOMATOUS STRICTURE OF THE COLON.

By W. J WALSHAM, F R C S ENG,

SURGEON TO, AND LECTURER ON SURGERY AT, ST BARTHOLOMEW'S HOSPITAL, EXAMINER IN SURGERY ROYAL COLLEGE OF SURGEONS OF ENGLAND, ETC

I HAVE chosen the diagnosis and treatment of malignant stricture of the colon for disquisition because during the last few years have had some 10 or 12 cases under my own care and have had the benefit of seeing a number of others under the care of my colleagues at St. Bartholomew's Hospital. By stricture of the colon I, of course, mean obstruction to the lumen of the bowel depending upon organic change of its walls I confine my remarks to carcinomatous stricture because this is the most common form and also for the purpose of limiting whatever discussion may follow my paper.

I will discuss the subjects under the following heads first, that the common form of carcinoma of the colon—namely, the columnar celled—is one of comparative benignity and may remain for a considerable time a purely local disease limited to the wall of the bowel; secondly, that this being the case its early diagnosis is of such importance and justifies us when in doubt in making an exploratory incision, since if the growth is removed early with a wide margin of healthy bowel-wall the patient may be completely cured, or, stopping short of this, may enjoy several years of comfort before secondary deposits in the glands and internal viscera terminate his life, and thirdly, that when, as is too frequently the case, symptoms of acute obstruction have come on before surgical aid is sought it is better to operate in two stages, in the first place to do a preliminary colotomy with or without the withdrawal of the carcinoma on to the abdominal parietes, and in the second place when the patient has thoroughly recovered from the deleterious effects of the obstruction to remove the carcinomatous portion of the bowel and unite the ends of the bowel above and below

I will now discuss the question under each of these heads, giving illustrations from cases that have been under my own care or that I have had opportunities of observing under the care of colleagues First, that columnar celled carcinoma the most common form is a comparatively benign growth and may remain for a considerable time a purely local disease I need not say much under this head The local origin of this form of carcinoma is, of course, well recognised by surgeons, but I am not so sure that we all are so familiar with the fact of its comparative benignity In many of the cases I myself have had to deal with, even although the lumen of the colon has been so reduced as barely to admit a small quill, the growth has been markedly limited, affecting often not more than an inch of the long axis of the bowel, which it causes to become hard, contracted and puckered forming a little mass of about the size of a walnut or Tangerine orange and feeling to the fingers when introduced through an exploratory incision into the abdomen very like a small lump of scybalous fæces, and although in many of these cases the contraction was often so great that only fluid fæces could dribble through, still no lymphatics or glands could be felt enlarged, and in several cases that I have met with in the post-mortem room of similar growths there has been actually no glandular enlargement or secondary deposits in any of the organs Two examples from my own practice bear upon this point Eight years ago I removed with the help of my friend Dr H J Ilott at the Cottage Hospital at Bromley a carcinoma of the cæcum and brought the ends of the divided gut together with Senn's plates. This patient made an uninterrupted recovery, and through the kindness of Dr Ilott I was able to examine her when I started putting these few notes together a few weeks ago She was still in the best of health and had no bowel trouble whatever, nor on careful palpation of the *abdomen could anything abnormal be detected. During the* early part of 1898, that is, three years ago, I removed another such localised mass, but from the sigmoid of an

enjoying good health

—namely, the import-

typical symptoms of

en so far advanced as seriously to obstruct the lumen of the bowel we are most of us familiar—namely, that the patient gives a history of having had one or more, often two or three, attacks of complete constipation lasting for several days to a week and attended by abdominal pains and distension but relieved by purgatives and enemata, that vomiting has only appeared late during the last attack and is probably not of a feculent character, that the abdomen has been gradually becoming distended and probably bulges more in the right flank than in the left, that nothing can be felt in the rectum or through the abdominal parietes if there is much distension; and that notwithstanding the absolute constipation the patient is not collapsed, his temperature is not raised, nor is he, except that he suffers spasms of pain and from time to time is distressed by the vomiting, apparently very seriously ill. Given such symptoms most of us, I imagine, would venture to diagnose stricture of the colon, and where the patient is advancing in years and has been losing in weight would probably not be wrong in pronouncing the case malignant. Although even when the carcinoma is so far advanced as to produce symptoms such as the above the disease may still be local, as in the two cases I have just quoted, yet there must be a grave chance of dissemination having already occurred or of the growth having formed such extensive adhesions to surrounding parts as to preclude surgical interference In a case of carcinoma of the cæcum and in another of carcinoma of the ascending colon on which I operated two or three years ago it was found on exposing the *growth that its removal, in consequence of* the matting together of neighbouring intestines, was quite out of the question, so in one I short circuited the intestines by a Murphy's button and in the other opened the cæcum and established an artificial anus Though both patients recovered from the operation, yet they succumbed within six months from dissemination of the disease in internal viscera.

What are the symptoms then that should arouse our suspicions of carcinomatous stricture whilst still in the early stage? A review of the history of my cases leads me to attach importance to the following (1) indefinite symptoms of abdominal disturbance, such as uneasiness, distension, eructations, constipation symptoms called by the patient and often by his medical attendant indigestion, but not referable to the stomach and not benefited by ordinary routine treatment, (2) attacks of pain or spasm referred to the colon, often of daily recurrence and having no special connexion with the time at which food is taken, (3) nearly always liquid stools with rarely a formed motion, (4) slowly progressive loss of weight, and (5) constant desire to defecate Those in family practice may say that they are constantly meeting with such symptoms and find them yield to careful dieting, judicious drugging, rest, and change of air and scene, and no doubt this is so but I have been greatly struck with the fact that in those cases in which I have taken a careful history and rigorously cross-examined the patient such symptoms have been almost invariably the precursors of the serious attack of obstruction for which I have been called in. Thus to quote one or two examples from my note books In the summer of 1899 I was asked to see a patient with serious obstruction by my friend Mr P E Wallis of East Grinstead. The patient had suffered from obscure abdominal symptoms such as those I have mentioned and had consulted two or three eminent practitioners in town who had put down his symptoms to indigestion gastritis enteritis, &c., and had treated him for such without relief In passing my finger into the rectum just within reach I detected a columnar celled carcinoma which had unfortunately too extensive attachments to admit of a removal In a second case—that of a medical friend who consulted me some years back on account of piles and a small internal fistula—indefinite abdominal symptoms which he attributed to his local trouble had existed for a few years In addition to loss of appetite eructations distension after food, and constipation he had continually recurring spasm and pain in the region of the colon and so constant was his desire to defecate that, as he told me, he had to spend half his mornings in the water-closet, nothing, however, passing but a little slime and mucus unless he had taken a strong purgative. Beyond the piles and fistula nothing could be felt in the rectum or on careful palpation over the sigmoid. He was gradually losing weight and I felt convinced that he had a stricture and impressed upon him the desirability of an exploratory incision in the left inguinal region. This he would not consent to, preferring to take the view that his trouble was the result of reflex spasm of the bowel consequent upon the irritation of his hæmorrhoids—an opinion in which he was supported by some of his medical friends. He, therefore, got a surgeon to remove his piles (I would not do it myself), but, as I expected, this did not relieve him, and some 12 months or so later complete obstruction set in and inguinal colotomy had to be performed. A growth was then discovered but too late to permit of removal. My contention, then, is that given a patient with indefinite symptoms of indigestion, with constant daily attacks of pain and spasm, and with constipation or occasionally what is called diarrhœa unrelieved by ordinary remedies and dieting, that the rectum should be examined and the colon carefully palpated, if necessary under an anæsthetic, when, if nothing is discovered, he should be periodically weighed, and if he steadily loses in weight and the symptoms do not seem to clear up that an exploratory incision should be made.

And this brings me to my third and last point—the treatment—first, during an attack of acute obstruction, and, secondly, when the growth is felt or discovered by exploration before acute obstruction has supervened. In either case the indication is to remove the growth and to restore the continuity of the divided intestine. When the symptoms are acute my own experience has led me strongly to advocate dividing the operation into two or even three stages. To attempt a complete operation, which must necessarily be lengthy in a patient with acute obstruction, perhaps of a week or ten days' duration, is to court failure. Both the local and the general conditions are unfavourable. The bowel above the stricture is dilated and distended with liquid fæces and its walls softened or even inflamed, whilst the bowel below is collapsed and shrunken. Notwithstanding the use of clamps to the distended bowel or the drawing off of its contents previously to excising the growth there must be a serious risk of fæcal soiling of the peritoneum even if the growth with the loop of the bowel in which it is situated can be drawn out of the wound, and then there is the further difficulty of uniting the distended portion to the collapsed portion owing to the difference in their calibre. But the growth may not present at the wound and to search for it amongst distended and overcharged coils of intestine which constantly tend to protrude through the incision is a procedure fraught with danger; not only do such manipulations prolong the operation, a most serious fact in itself, but they may cause so much injury of the peritoneal coat of the bowel that the bacillus coli and other micro-organisms contained in the fæces and probably already invading the mucous and muscular coats may penetrate the serous layer and set up acute septic peritonitis. Moreover, the general state of the patient is most unfavourable for any prolonged operation. Think for a moment of the state he is in. His stomach is completely upset by regurgitation of fæcal matter from the intestines, he is exhausted by the constant vomiting and pain and the want of nourishment (for even if nourishment has been given, as is unfortunately too often the case, by the over-anxious friends it is vomited and not assimilated), and his vital powers are depressed by the ptomaine absorption which has been taking place from his over-charged intestines. We all learn by experience, and I have to confess to losing a patient through the desire to complete the operation at one sitting. I was asked to see a man, aged about 60 years, a little distance in the country. He was suffering from an attack of complete abdominal obstruction of some weeks' duration. I diagnosed stricture of the ascending colon and in cutting down on the colon my diagnosis was verified. I removed the growth and united the bowel above to the bowel below by means of a Murphy's button. All went well for from 24 to 36 hours, when the softened intestine above gave way and the patient collapsed and died. I cannot help feeling that had I contented myself with making an artificial anus and subsequently removing the growth and restoring the continuity of the intestine when the effects of the acute obstruction had passed off the result might have been different.

Having given my reasons against resection during an acute attack let me now speak of the practice that my personal experience leads me to advocate. It is as follows. Should the symptoms point to the obstruction being in the sigmoid left inguinal colotomy should be performed and the sigmoid drawn into the wound. If found distended it is clear that the obstruction is below. Now assuming the distension of the abdomen to be great, the patient elderly, feeble, and his condition grave, I advise fixation of the distended coil and its immediate drain by a Paul's tube. This operation should take less than a quarter of an hour, and then in from 10 days to a fortnight's time, or as soon as the abdomen has become flat, the tongue clean, the appetite regained, and the patient's general health sufficiently restored, the growth may be safely dealt with. Thus during the year 1898 a woman, aged 65 years, was admitted under my care into Lawrence Ward. She had frequent attacks of vomiting and constipation and had been losing flesh. Her bowels had not been open for 14 days before admission. Her abdomen was immensely distended; she was constantly vomiting fæcal matter. Left inguinal colotomy was performed. The patient was so desperately ill and the coils of bowel that presented in the wound were so distended that no exploration was made, but the sigmoid was drawn out and a Paul's tube inserted into it. She was at once relieved and progressed satisfactorily in every way. A week or two later a growth was discovered in passing the finger into the bowel through the colotomy wound about three inches down the distal portion of the gut. When her general condition was sufficiently improved a small incision was made below the colotomy wound, the loop of the intestine containing the growth was excised, and the intestine, united end to end by Murphy's button, returned into the peritoneal cavity and the parietal wound closed. 12 days later the button passed out of the rectum. Injections could now be freely thrown from the anus through the colotomy wound and *vice versâ*. Still later the colotomy wound was closed without opening the peritoneum and had quite healed except at one spot when she left the hospital. A fortnight ago one of my dressers visited her at her house in Clerkenwell for me and found her in excellent health without any sign of recurrence and no abdominal trouble whatever. In a second case with similar symptoms of 10 days' duration, pointing to obstruction in the sigmoid, in which the patient's condition was also too serious to admit of any exploration, I resorted to inguinal colotomy and a Paul's tube as in the former case, and here again, when the patient had recovered from the obstructive attack, made an elliptical incision around the colotomy opening, drew out the portion of sigmoid that had been opened at the colotomy together with about six inches of the intestine below, in which I discovered, at about four inches from the colotomy opening, a growth of the size of a Tangerine orange. The sigmoid was divided above the colotomy wound and below the growth, the intervening portion removed, and the ends united by Murphy's button, dropped back into the peritoneal cavity, and the external wound closed by sutures. No enlarged glands were felt in the mesentery. Healing occurred by the first intention and the button was passed on the tenth day. When the patient left the hospital she was in the best possible health and spirits, and my friend Mr. R. Mathews of Bickley, who sent her to me, told me only the other day that her condition was still most satisfactory. In neither of these cases, for reasons already given, was any search for the growth made, my whole aim being to get the patients off the operating-table in the shortest time possible. In a third case, a man, aged 49 years, the symptoms, though severe, were less acute than in the preceding cases. I therefore on finding the sigmoid distended passed my fingers along it towards the pelvis and discovered and drew out a growth. This, together with about two inches of the distended sigmoid above the growth, was fixed in my usual way by an hysterectomy pin passed through the mesentery and a Paul's tube inserted into the bowel above the growth. The operation took less than 20 minutes. Huge quantities of fæces flowed away for the next few days to the immense relief of the patient, who had no bad symptom, and at the end of a fortnight I made an incision around the colotomy wound, drew out healthy sigmoid together with the portion of sigmoid through which the Paul's tube had been inserted, and united the bowel above and below by a large-sized Murphy's button. The united intestine was then replaced and the parietal wound sutured. The button was passed on the twelfth day.

Fortunately for the surgeon carcinomatous stricture is much more common in the sigmoid than in other portions of the colon, but I have met with it in the splenic and hepatic flexure, ascending colon, and cæcum. Time will not permit me to enter upon the question of the diagnosis of the site of the growth—indeed, in any case one can only make an appropriate guess. When in doubt my practice has been first to look at the sigmoid and if this is found collapsed and the distension of the small intestines is great to close the wound and open the cæcum through a second incision on the right side. Where the distension, however, is not great it may be well to trace the sigmoid upwards before opening the cæcum. Quite recently my colleague Mr. Alfred Willett on tracing the sigmoid in such a case came upon the growth in the splenic flexure and with a little traction was able to bring it out of the wound and to insert a Paul's tube into the bowel above. This patient made an excellent recovery from the operation but died later from secondary growths in the viscera. When the cæcum has been opened and the patient's condition has sufficiently improved, if no growth can be detected on palpation or with a finger passed upwards through the colotomy opening it is perhaps better to explore the colon through an incision in the middle line as freer access is in this way gained. In these cases in which the growth can be felt in the line of the colon either with or without an anæsthetic and the symptoms are not acute, the right course is clearly to make an incision over the swelling and remove the carcinoma if feasible, or if not to short-circuit the bowel. I have before me two specimens of the cæcum, one removed eight years ago and the other about a year ago; both patients when last heard of were well.

Finally, a very few words as to where the exploratory incision should be made where the symptoms lead us to suspect a stricture but no growth can be felt, there are no indications as to its situation, and acute obstruction has not supervened. For such cases a median hypogastric incision is preferable, since through it not only the condition of the colon but that of the small intestine can be investigated as well. Thus, in a case of the kind on which I operated quite recently at Bromley the stricture, contrary to our expectation, was in the small intestine and was readily dealt with through this incision. Had the growth been in the colon and inaccessible from the median incision, after locating its actual position I should have made a second incision over it and dealt with it there.

In conclusion, let me briefly recapitulate the points I have endeavoured to make out: first, that the columnar-celled carcinoma is one of the least malignant of the cancers, and although it may have led to almost complete stenosis of the gut there may still be no dissemination; secondly, since, as in other forms of carcinoma, dissemination at length occurs it is desirable where symptoms such as have been mentioned are present to make an exploratory incision; and lastly, if acute obstruction has supervened the safest course is merely to open the colon above the growth and to deal with the latter after the acute stage has subsided.

THE SERO-THERAPEUTICS OF PLAGUE.

BY JOHN BROWNLEE, M.A., M.D. GLASG.,
D P.H. CAMB.,
PHYSICIAN SUPERINTENDENT, CITY OF GLASGOW FEVER AND SMALL-POX HOSPITALS, BELVIDERE.

IN giving an account of my experience of the treatment of patients suffering from plague with Yersin's serum, as received from the Pasteur Institute of Paris, it may be well to point out that the disease as it occurred in Glasgow was apparently of a much milder type than is that usually seen in the East. The number of cases was too small to admit of statistical comparison between those treated with the serum and those not so treated, and on account of the mild character of the epidemic comparison with the statistics of other epidemics in other countries is not possible. Consequently the value of the treatment can only be gauged by a careful consideration of each case in detail.

The first two cases in which the serum was given were those[1] of T. H—— and C. M——, already reported in THE LANCET.[1] In both these cases the only organism obtained in puncturing the buboes was the bacillus pestis. The first of these cases belonged to the septicæmic variety of plague with multiple bubo. The prognosis was bad. Within 36 hours of the administration of the serum the temperature fell nearly to normal and the patient was apparently out of danger. In the second case, which appeared to be an example of the fulminant type of plague, an injection of 20 cubic centimetres of the serum intravenously and of a like amount subcutaneously was followed within 24 hours by a complete cessation of symptoms. Both patients were excessively ill and in both the subsidence of the symptoms was marked and immediate. There were, it is true, some cases of plague untreated by the serum in which there was a critical fall in the temperature, but in these the disappearance of the mental obscuration which accompanied the fever was much more gradual and the convalescence more tedious. In both the cases under consideration a symptom was present not observed in any of the other cases which ended by crisis—viz., a few hours after the injection a copious sweating occurred over the whole body.

The next three persons treated by serum suffered from a milder type of the disease; in only one was the prognosis doubtful. The first, Mrs. B—— (Case 1), was a case with right inguinal bubo from which on puncture a pure culture of bacillus pestis was obtained. The patient on admission did not seem sufficiently ill to require an injection of the serum, but two days later, as the symptoms had considerably advanced, 20 cubic centimetres were injected subcutaneously into the abdominal wall. The next day the symptoms had somewhat abated. The pain in the bubo was less and the reddening of the skin over the swelling was not so marked. In the evening, however, the patient's condition was again not so good, and by the following morning the temperature had again risen. The local condition had advanced and the infective process had extended so as to involve the lymphatic glands above Poupart's ligament and also the deep inguinal glands. A further injection of 20 cubic centimetres of the serum was then given, this time into one of the veins of the right arm. An immediate improvement was noted. Six hours after the administration of the serum the temperature had become normal and on this occasion no subsequent rise took place such as had occurred after the former dose administered subcutaneously. In a second instance the result was equally interesting. The case was that of Mary M—— (Case 2). This patient, a girl, 14 years of age, suffered from a bubo in the left axilla. The point of entry of the infection was evidently located in the back, where, as described in the full report, a small pustule was situated, which was proved bacteriologically to contain the plague bacillus. The external local condition afforded a visible index by which the therapeutic effect of the remedy could be gauged. Here again a subcutaneous injection of the serum was followed by a temporary improvement as regards the bubo, the pain being considerably less on the next day, but no improvement could be seen in the pustule above mentioned. A recrudescence of the disease occurred likewise in this case, with a rise of temperature to 102°F. A second pustule began to form on the back, while the erythematous zone surrounding the first occurring pustule became rather larger. Here again the intravenous injection of the serum in a dose of 20 cubic centimetres was followed by an immediate improvement. Within 24 hours a slough in the centre of the original pustule had separated and the inflammatory zone had almost disappeared, while the second commencing pustule had completely aborted The patient six hours after the administration of the last dose of serum spontaneously expressed herself as feeling very much better. The temperature by the same time had fallen to normal and, as in the other case just mentioned, it remained so without subsequent rise. Convalescence from this point was rapid and uninterrupted. The third case belonging to this group was that of Mrs M—— (Case 3) This patient, the mother of the preceding one, was aged 41 years She had a right inguinal bubo. On admission the temperature was 102.4° F., the pulse was 104, and the respirations were 24 The patient was evidently ill, though a fatal issue was not expected. A subcutaneous injection of 20 cubic centimetres of the serum produced almost no effect, but there was, if anything, next day a lessening of the pain in the bubo. Thirty-six hours later a second injection of 20 cubic centimetres was given intravenously. As in the other two cases just noted, there was observed an almost immediate improvement, the patient expressing herself as being much better six hours after the remedy had been administered. The temperature fell to normal within 24 hours and remained there.

---

[1] For particulars of these and other cases of plague in Glasgow see THE LANCET of Sept 8th (p. [illegible]), 15th (p. 827), 22nd (p. 877), and 29th (p. 904), 1900.

The points to be noted with regard to all these cases are that the subcutaneous injection of the remedy produced little effect, and that of a temporary nature, while the administration of the serum intravenously was followed in each case by an improvement which was easily seen in the subsidence of the signs of illness and which besides was spontaneously borne witness to by the patients themselves.

The serum was also administered to four persons in whom the disease progressed to a fatal issue. One of these needs no mention, as he did not come under treatment till the fourth week of the illness, at which period an extensive secondary pyogenic infection of the sloughing bubo had occurred. Each of the other three require special notice. The first of these in point of time was Mrs. M—— (Case 4). This patient was the daughter of the last-mentioned patient and the sister of M. M——, also already referred to. She had for some time prior to the onset of illness experienced considerable privation. On admission she was extremely ill and premature labour was in progress. No apparent benefit resulted from the administration of the remedy, the patient dying within about three days from the commencement of the illness. In this case serum was administered on the evening of admission—20 cubic centimetres into a vein of the right arm and 20 cubic centimetres into the subcutaneous tissue of the flexure surface of the left thigh, so that it might drain directly into the bubo, which was situated in the left groin. Next day 20 cubic centimetres additional were administered nto the subcutaneous tissue of the abdomen. Though only the plague bacillus was obtained on culture from the bubo in this case both before and after death, yet in the retroperitoneal glands it was demonstrated that the infection was a mixed one, as considerable numbers of colonies of a diplococcus, staining by Gram's method, were seen in sections of these. This patient was so enfeebled by the privation which she had undergone that she would in all probability not have survived her confinement apart from the attack of plague. So that, both because the case was not uncomplicated and because of the patient's weakness, the result cannot be said to weigh one way or the other in appraising the value of the serum treatment. But it must be noted, as indicating that the serum had some considerable influence on the organism, that the bubo revealed on examination after death no plague bacillary forms which did not bear evidence of the most profound degeneration, while those obtained from the other organs of the body showed no evidence of being in any way altered. On the same day the brother of this patient was admitted (R. M——, aged 11 years, Case 5). His history, which is recorded below, indicates that the infection here also was from the first of a mixed nature. When in the course of the second week of observation one of the buboes had proceeded to abscess the only organism recovered from the discharge after incision was the staphylococcus pyogenes aureus, and that in great numbers. As there were no means of infection of this bubo prior to its incision, it is highly probable, considering the septic course of the temperature, that the double infection was primary. Of all the cases treated with serum early in the course of the illness this is the only one in which no effect of any kind was noted. The only other case in which the serum was administered was that of M. G—— (Case 6). This was, though fatal, one of the most interesting in some of its features. The patient was a child, six years old. (Puncture of the bubo in the right groin on admission resulted in the discovery of the plague bacillus in its typical forms.) On admission she was profoundly ill and in a state of almost complete unconsciousness. When disturbed she cried out harshly and struggled to be let alone, but otherwise took no notice of her environment. As recorded in the report, intravenous injection was attempted without success, but in the first 48 hours after admission she received 100 cubic centimetres of the serum into the subcutaneous tissue, chiefly of the lower part of the abdomen. On the morning of the fourth day after admission a marked improvement was noted, insomuch that the child for the first time recognised her mother and smiled to her. From this point, however, there was a rapid advance in the gravity of the case, and death supervened with the usual symptoms of heart failure on the eighth day of illness. The same appearance was noted in this case as in that of Mrs. M. (Case 3) above referred to—viz., that the bacilli found in the bubo which received the drain of a large part of the serum administered were markedly degenerated, while those in the deeper organs of the body were unaffected and very virulent.

A general review of the action of Yersin's serum falls to be considered under two heads—firstly, the prophylactic action; and secondly, the curative action.

1. *The preventive action of the anti-plague serum.*—Of the healthy persons who had been in contact with plague and who received a prophylactic injection of the anti-plague serum two developed the disease. One of these was a maid attached to the service of the plague wards. From her buboes the specific bacillus of plague was recovered, and at the appropriate time after the disease was over her blood gave the typical agglutinative reaction in a marked degree. The other (Mrs. G——, Case 7) was the mother of one of the patients who died and who is noted above (M. G——, Case 6). During the course of the disease the pyrexia was fairly high, but she never gave the impression that she was dangerously ill. The three factors which might have contributed to produce this high temperature are noted in the annexed report. These two cases prove that a dose of 10 cubic centimetres of Yersin's serum administered subcutaneously does not afford complete protection, yet it is a fair presumption that a certain degree of immunity is afforded, as the symptoms in both cases were of great mildness. This corresponds with what has been frequently observed with regard to the action of diphtheria antitoxin when used as a prophylactic. Immunity is not a certainty, but if the disease becomes established the attack is almost certain to be slight.

2. *Curative action.*—A general review of the facts given above and a consideration of the reports of the individual cases will, I think, justify the following conclusions: First, that subcutaneous injection of the serum is not of any great curative value. This is probably not due to the blocking of the lymphatics during an attack of plague, as has been suggested by some, in view of the fact that absorption of the serum by healthy persons is no more rapid than that seen in the plague patients. The failure in action is therefore much more likely the result of the lymphatic system exercising a distinct action as a biological filter on the serum, such as exists in other organs. In this way the antitoxic substances of the serum are retained largely in the glands which drain the area into which the injection is given, so that only the more inert portions of the serum reach the general circulation. It was noticed that the lymphatic glands connected with the area into which the injection was made in healthy persons enlarged for some days thereafter. This is not a proof that such a filtering action as above indicated takes place, yet it shows that some constituent of the serum having an irritant action is retained, and if the glands possess the power of filtering out certain ingredients of the serum there is no reason to doubt, in the light of what has gone before, that this may include the active antitoxin. The case of Mrs. M—— (Case 4) lends some clinical support to this view. The inguinal bubo, into the drainage area of which the serum had been injected, showed post-mortem evidence of a potent local effect in the marked degeneration of the bacilli, while the organisms found in other parts of the body were quite normal. It is therefore evident that subcutaneous injection of the serum can be efficient only in cases where the infection is localised to a bubo and has not become general. Secondly, the intravenous injection of the serum seems, in most cases, to produce a most marked therapeutic effect, even when given late in the disease. This is exemplified in the case of T. H——. In those cases, on the other hand, where double infection has existed from the beginning, its action is greatly lessened. In conclusion, it is probable that the doses given were in general too small, and should an opportunity again arise of using this remedy large initial doses of 60 cubic centimetres and upwards would be given intravenously. Probably it would be advisable, if using the serum subcutaneously at all, to inject it only into the area drained by the lymphatic system which leads directly to the bubo.

CASE 2.—Mary M——, aged 14 years, was admitted on Sept. 15th, 1900. The patient on the night prior to admission became gradually very ill with severe frontal headache. On the day of admission sickness and vomiting were the most prominent symptoms, but she also complained of a tender swelling in her left axilla. On admission the temperature was 99.8° F., the pulse was 120, and the respirations were 28. The face was of an earthy colour with an anxious look, the lips were dry, and the skin was hot to the touch. The tongue was dry over the dorsum, but the edges were red and moist. There was no rash. Four inches from the base of the axilla there was a single small, hard, tender gland which was freely moveable; at the border of the latissimus dorsi behind there was another gland rather more obvious, but not so tender. No other complaints were made at the time of admission. No serum was given as the patient did not appear to be particularly ill. Next evening the temperature had risen to 101.5°. It was then noticed for the first time that the patient had on the back, about the level of the spine of the eighth dorsal vertebra, a small pustule. This pustule showed certain distinctive features. It was about a quarter of an inch in diameter, the centre being depressed and covered by a scab while the edge was raised and formed of a ring of minute pustules. An inflammatory zone of about two and a half inches surrounded this pustule. Direct microscopical examination of the material obtained from the pustule showed the presence of numerous quite characteristic plague bacilli, whilst in many of the leucocytes degenerating forms of the same organism were apparent. Cultures were made and a characteristic growth of the organism was obtained. Twenty cubic centimetres of serum were injected subcutaneously. Next day (Sept. 17th) the temperature had fallen to normal and the patient was somewhat better, but although the gland in the axilla was a little less tender the pustule showed no signs of diminishing. In [illegible] appeared on the left [illegible] it's temperature was [illegible] worse. The second area of inflamed skin had now a yellowish centre, as if of commencing pustulation. At mid day 20 cubic centimetres of serum were in[illegible] In the evening the [illegible] very much better an[illegible] day (Sept. 19th) the patient felt very well. The slough in the centre of the pustule had separated, leaving a healthy granulating surface, and the second erythematous area in the flank had almost completely disappeared. From this point convalescence was uninterrupted.

CASE 4.—Mrs. M——, aged 20 years, was admitted on Sept. 15th, 1900. The duration of the illness was a little doubtful, owing to the difficulty of obtaining an accurate history of the patient from her friends. It was, however, certainly under 48 hours. The onset had apparently been very severe, headache, pain in the back, diarrhœa, and great prostration being the most marked symptoms. The patient was very much emaciated, and had undergone great privation for some time prior to admission. The face was pallid, the lips were dry and covered with sordes, and the tongue was likewise dry with a brown fur. The temperature was 102.6° F., the pulse, which was soft and rapid, numbered 140, and the respirations were 40. The patient was eight and a half months pregnant, and on admission labour was already in progress. The only physical signs observed in the lungs were some subcrepitant râles at both bases. There was a large, indurated, and very tender bubo in the left inguinal region. No rash was observed. On the evening of admission 20 cubic centimetres of serum were injected intravenously and 20 cubic centimetres into the area immediately below the left groin, so that it might drain directly into the bubo. At the time of the injection the temperature had fallen to 99.6°, and the patient was much collapsed. At 4 A.M. the os was found to be fully dilated, and as by this time the patient's general condition was one of extreme gravity instrumental delivery was at once effected. The child was born asphyxiated, and after much trouble was resuscitated. No gross lesion of the placenta could be observed. After the birth of the child the patient rallied a little. The temperature rose to 103.8°, the tongue and lips became cleaner and moister, and the patient expressed herself as feeling a little better. On Sept. 16th 20 additional cubic centimetres of serum were injected subcutaneously into the abdominal wall. During the day the patient's state became more and more grave, and she died at 11.50 P.M. A pure culture of the plague bacillus was obtained from the bubo on admission, and also from the blood. On examining the bubo after death no plague bacillary forms which did not bear evidence of the most profound degeneration could be discovered, though in the spleen and other organs of the body typical unaltered forms were easily seen.

CASE 3.—Mrs. M——, aged 41 years, was admitted on Sept. 16th, 1900. The history of the illness was a little difficult to obtain accurately as the patient was considerably out of sorts for some weeks, but it probably began two days prior to admission. The chief symptoms were severe headache and general malaise; on the day prior to admission she noticed a small tender swelling in the right groin. On admission the temperature was 102.4° F., the pulse was 104, and the respirations were 24. The patient complained of very severe headache. The tongue was dry and the face was very anxious looking. In the right groin there was a small bubo of about the size of a pigeon's egg which was exceedingly tender. There was also some induration in the tissues round the gland, but the skin was not adherent. The bowels were constipated. The patient was evidently ill. On the evening of admission 20 cubic centimetres of serum were injected into the abdominal wall. Next day there was no change in the patient's condition with the exception of the fact that the bubo was, if anything, less tender, and as on the 18th no further improvement had taken place 20 cubic centimetres of the serum were injected into a vein of the right arm. In the evening great improvement had taken place in the patient's sense of well-being and she expressed herself as feeling very much better. The tongue was more moist, the headache had gone and the pain in the bubo was much less. From this point convalescence was good, no rise of temperature occurring subsequently.

CASE 1.—Mrs. B——, aged 29 years, was admitted on Sept. 14th, 1900. The patient was the wife of one of those who were engaged in the removal of plague infected clothing and was probably infected by her husband. The illness began on the day prior to admission with severe frontal headache and rigor, pains in the limbs, and severe pain in the back. There was no sickness, vomiting, or diarrhœa. On the morning of the day of admission pain was felt in the right groin and on examining this region she perceived a small lump, which was very tender to the touch. The temperature on admission was 100.8° F., the pulse was 96, and the respirations were 32. On admission the patient did not look very ill, but the face was somewhat flushed and anxious. The eyes were slightly injected and the pupils were normal. The tongue was moist and slightly furred. The heart and lungs, on physical examination, showed nothing noteworthy, with the exception of a few wheezing râles. A bubo was present in the right groin, chiefly involving the horizontal chain of lymphatic glands below Poupart's ligament. The vertical chain was only slightly involved, and there was some œdema in the surrounding connective tissue. The skin in Scarpa's triangle was reddened. This bubo was exceedingly tender. Next day the patient was somewhat better and as the temperature had fallen no serum was given. On the 16th the temperature was still normal, but the symptoms advanced during the day, and in the evening the temperature rose to 101.2°. The bubo was now considerably larger, the connective tissue more œdematous, and the skin more inflamed. 20 cubic centimetres of serum were therefore injected into the skin of the abdomen. Next day the temperature had fallen and the pain in the bubo considerably abated. On the morning of the 18th, however, the local conditions had again advanced, with extension above Poupart's ligament to the deep inguinal glands. The œdema was much increased and the redness had extended down the side of the thigh. Consequently 20 cubic centimetres of serum were injected into a vein of the right arm. Towards evening a great improvement in the patient's condition had taken place and she both looked and felt very much better. Next day the temperature was normal and falling to slightly sub-normal in the evening remained so. Improvement was rapid, the bubo softened and ruptured spontaneously on Sept. 23rd. Convalescence was good. A pure culture of the plague bacillus was obtained on admission from the bubo. On rupture the discharge proved sterile but contained many degenerate forms of bacilli, some being free and others contained in the leucocytes.

CASE 5.—R. M——, aged 12 years, was admitted on Sept. 16th, 1900. The patient became ill on the evening of Sept. 14th with slight headache. Next morning he was much prostrated and the headache had become very severe. He also made complaint of acute pain in the left axilla, and this seems to have been from that time up to his admission to hospital his most clamant symptom. No history of rigor, sickness, or vomiting could be obtained. On admission his temperature was 102·4° F., the pulse numbered 130, and the respirations were 36. The patient looked very ill. The face had the characteristic ashy pallor, with drawn brows. The lips were dry and fissured; the tongue was dry and brown on the dorsum, but moist and red at the edges. The eyes were clear and the conjunctivæ were not injected. There was some mental obscuration, dependent partly on the grave prostration, but partly, also, on his continual dread of the pain consequent on his being even carefully handled. The slightest movement caused the most acute pain, referred chiefly to the left axilla. Palpation in this region revealed the presence of a small indurated gland, which was very tender. Unlike, however, what had been observed in other cases, the tenderness was not limited to the immediate neighbourhood of this bubo, but extended to the outer portion of the pectoral region. Physical examination of the lungs revealed nothing noteworthy beyond a few localised patches of crepitant râle. There was no dyspnœa and no evidence of pulmonary engorgement. The heart's action was very feeble, and the apex impulse was widely diffused. The pulse was full and bounding, but of very poor tension. The spleen was not enlarged. The urine contained no albumin. The bowels were constipated. Twenty cubic centimetres of serum were injected subcutaneously and also 20 cubic centimetres into the right median cephalic vein on the evening of admission. On Sept. 17th the patient's general condition seemed rather better, the tongue being moister and the expression of the face less anxious. There was also less tenderness in the left axilla. On the 18th his condition was worse and an additional dose of 20 cubic centimetres of serum was injected subcutaneously in the afternoon. On the 19th 20 cubic centimetres were injected intravenously. Next day there was no apparent improvement, the respirations were more frequent, and an increased amount of crepitant râle was audible over both lungs. There was, however, no cough and no sputum could be obtained. At the outer part of the left pectoral region was an indefinite swelling, feeling, on palpation, as if situated under the pectoral muscle, suggestive of deep abscess formation. The axillary bubo was no longer tender. As the temperature since admission seemed to indicate a pyogenic infection, and as the serum had no effect on its course, no more serum was given, on the assumption that the patient was now suffering from the effects of a double infection rather than from plague alone. This supposition was borne out by the alleviation of the pain and tenderness at the site of the bubo and the recent swelling under the pectoral muscle. By the 25th this swelling gave definite signs of deep fluctuation and was incised after freezing the skin, giving exit to a sero-purulent fluid which, on cultivation, gave a pure culture of the staphylococcus aureus, but no bacillus pestis was isolated. The abscess was found to be situated under the pectoralis minor. From this time the patient's condition became rapidly worse and he died on Sept. 28th. The respirations were very rapid, but the patient was so ill that he was not disturbed by physical examination. Throughout the urine remained free from albumin, except on Sept. 22nd and 23rd, when the specimens obtained showed a faint trace.

CASE 7.—Mrs. G——, aged 24 years, was admitted on Sept. 19th, 1900. The patient became ill on the day prior to admission. The initial symptoms were not of great severity, slight headache and a feeling of general malaise only being complained of. Coincident with these symptoms a tender swelling was discovered by the patient herself in the right groin. It is to be noted, however, as accounting, perhaps, for the comparative mildness of the onset, that seven days prior to the commencement of illness she had received a prophylactic injection of 10 cubic centimetres of Yersin's curative serum. On admission she did not look as if she were very ill. Frontal headache of moderate severity was complained of, and in the right groin involving the vertical chain of glands the above-mentioned swelling, which was of about the size of a walnut, was observed. The glands were more or less adherent to one another and also to the subjacent tissues, but the overlying skin was freely moveable and not inflamed. The tongue was moist and clean; the bowels were constipated. The illness had interrupted the suckling of a three-months-old child, and on this account the breasts were enlarged and tender. The course of the illness, however, was short, lasting in all about five days, and the only clamant symptom complained of was the frontal headache. The fever was maintained at a high level for two or three days, ranging between 100° and 104° F., but other symptoms were not present in like severity. The pyrexia might be regarded as due to three factors—first, the attack of plague, probably the most important; secondly, the condition of the breasts, which became very large and tender; and thirdly, serum fever. The maximum temperature occurred on the ninth and tenth days after the prophylactic injection of serum—i.e., at the period when the pyrexia due to serum usually made its appearance. On Oct. 4th spontaneous rupture of the bubo took place and from the discharges obtained on that day virulent plague bacilli were recovered. From this point onwards convalescence was rapid and complete.

CASE 6.—Mary G——, aged six years, was admitted on Sept. 19th, 1900. This patient, who was the daughter of Mrs. G—— (Case 10[2]) and the niece of Charles McM—— (Case 1[2]), became ill on the day prior to admission with severe prostration and headache. On admission the patient's temperature was 101·2° F., the pulse was 146, and the respirations were 44. The aspect was that of a person acutely ill. The face was pale and somewhat cyanotic; the lips were dry and blue. The tongue was dry over the dorsum, but the edges were moist and clean. The child lay in a semi-comatose state and did not even recognise her mother who lay in the next bed. The right inguinal region was the seat of a swelling of about the size of a hen's egg and on examination this was seen to consist of a mass of enlarged and tender lymphatic glands. There was also some periglandular infiltration but no reddening of the skin. Examination of the lungs failed to detect anything noteworthy. On the evening of admission intravenous injection of the curative serum was attempted, but without success as the veins were very thin-walled and deeply embedded in a thick layer of adipose tissue. Twenty cubic centimetres of serum were therefore injected subcutaneously into the wall of the abdomen. Next evening the child was rather worse; the temperature was somewhat higher and the pulse was softer and more compressible. A second attempt to inject serum into a vein failed, and accordingly 40 cubic centimetres were again injected into the wall of the abdomen. The following morning the patient's condition was, if anything, slightly better, though she was still more or less unconscious. The pulse, however, was firmer, and the respirations were somewhat slower. A third attempt at intravenous injection having failed, 40 cubic centimetres of serum were injected for the third time into the abdominal wall. In the evening a very marked improvement was observed, the child having regained her natural colour, and being now quite conscious for the first time. She smilingly recognised her mother. The improvement, however, was not maintained beyond the following morning. On the evening of the 22nd the temperature again rose, and the pulse became very feeble. From this point onward the patient sank steadily. Death was associated with marked hypostatic congestion of the lungs, and was directly due to heart failure. No additional serum was given on account perhaps of undue timidity, for, as by this time moderately severe constitutional disturbance following on small doses of the serum had been frequently observed in healthy persons it was not deemed advisable to persevere with the treatment.

Glasgow.

A CASE OF PRIMARY HÆMORRHAGIC OTITIS MEDIA.

BY H. J. CURTIS, B.S. LOND., F.R.C.S. ENG.,
ASSISTANT SURGEON, ROYAL HOSPITAL FOR CHILDREN AND WOMEN, WATERLOO ROAD; LATE SURGICAL REGISTRAR, UNIVERSITY COLLEGE HOSPITAL, LONDON.

THE patient was a very intelligent hospital nurse, aged 35 years, who had just been enjoying a three months' holiday and had not resumed work. She had not been exposed to cold and had not suffered from earache, otorrhœa, or ear trouble of any kind until Nov. 13th, 1900, when at 8 P.M., two hours before retiring for the night, she began to suffer from noises which were referred to the back of the head, and which were about equally distinct on both sides of the middle line at about the level of the lambdoid suture. The noises were like bells ringing or water boiling. When the patient went to bed and lay down the sounds were no longer noticed. Excruciating pain was now for the first time experienced in the occipital region exactly where the noises had previously been. The patient was kept awake owing to the severity of the pain which became worse and worse for four hours, when at 2 A.M. the next day she experienced a feeling of something bursting inside the head at a point distinctly located just to the left of the occiput, no pain or other disturbance having been felt during all this time in either ear. The patient was therefore much surprised to observe that the sensation of something having given way in the back of the head was followed at once by a rapid flow of blood from the left ear, nothing coming from the right side. The blood was bright red at first and then darker. Two handkerchiefs were used to stanch the blood, though these were not saturated right through. The bleeding continued from 2 to 11 A.M., but by 9 A.M. the discharge had become as pale as serum, and between 9 and 11 A.M. only a few drops of this pale serum escaped. After the bursting sensation described the pain was at once considerably relieved, but though it became less severe it did not completely terminate. The patient could stand and there was never any giddiness until syringing of the left ear was ordered, thrice daily, by the medical attendant on the same day that the hæmorrhage ceased. Syringing was continued for two more days and then no further treatment was applied until the case came under my immediate care on Nov. 29th, 16 days after the onset of the symptoms. The pain in the back of the head had continued up to this date, being referred to the mid-line of the occiput and not being more marked on one side than on the other. The pain—except on the first night of the attack—had never been acute, but was dull and aching in character, and recently it had become decidedly less marked. Occasionally, especially on rising, the patient suffered from sensations of "swimming" in the head. Though she was not liable to catch cold she had suffered from relaxed throat when "run down." There was no family history of tuberculosis. She had never suffered from scarlet fever or measles.

---

[2] THE LANCET, Sept. 29th, 1900, p. 964.

Examination on Nov. 29th showed the hearing for ordinary conversation to be very good; the ticking of a watch, however, was heard by both ears at a distance of two and a quarter feet, only about half the normal distance for this watch. The left membrana tympani showed a large perforation involving most of the postero-superior quadrant and being almost occluded by dark blood-clot, Shrapnell's membrane also being dotted over with dried fragments of clot. The membrane elsewhere was somewhat opaque, retracted, and over-cupped. The right membrana tympani was rather thicker and more opaque than normal and over-cupped. A line of congestion was evident along the posterior border of the handle of the malleus. There was no sign of any previous perforation. Examination of the nasal fossæ, naso-pharynx, fauces, &c., showed both inferior turbinates and the right middle turbinate to be hypertrophied; there were chronic naso-pharyngitis with secretion and large granules on the back of the pharynx, &c., and a relaxed uvula, and the tonsils were a little enlarged. A specimen of urine obtained on the fifth morning after the initial attack was clear, of normal colour and odour, moderately acid, and of specific gravity 1027. No blood or trace of albumin or sugar was present. A well-marked indican ring was given with nitric acid; no bile was present. Examination of the chest showed that the heart and lungs were normal and that the pulse was quite normal in rate, force, and rhythm. Ophthalmoscopic examination showed both discs to be perfectly normal. Menstruation was scanty but fairly regular, seven-weekly, occurring never more frequently; there had been no periods of amenorrhœa recently.

By way of treatment gentle syringing with warm boric lotion twice a day to remove the blood-clot, &c., was ordered and rest for some days advised. When seen a week later (Dec. 6th) the patient reported that she had suffered from occipital headache and "singing" or "frying" noises in the left ear four days previously, but since that date there had been no headache or giddiness. She felt perfectly well. Examination of the left membrana tympani showed the blood-clot first noticed to have largely disappeared, leaving pieces of it thinly scattered about and allowing easier inspection of the interior of the middle ear through the perforation now rapidly closing. The head of the malleus, the incus, and apparently the chorda tympani were visible, as well as fragments of blood-clot lining in the inner wall of the tympanum. A watch was heard at a distance of 27 inches on the left side, compared with 41 or 42 inches on the right side. Self-inflation of the membranes by Valsalva's method could not be obtained on either side.

The patient was seen again on Feb. 27th, 1901. She was then perfectly well, but had had four attacks of headache located just above the external occipital protuberance. These had occurred quite suddenly, twice in December and twice in January. She attributed them to unusual exertion and anxiety in nursing cases of influenza. As well as suffering from headache the patient was giddy and vomited. She said that she very often felt slightly giddy apart from the onset of headache. She had also suffered from severe attacks of toothache lasting 12 hours or less. There had been no attacks of pain anywhere during February, but though the teeth were not painful she was confined to bed for four days with the left side of the face very much swollen, the temperature one night rising to 103° F. Examination of the left ear now showed that the perforation in the membrane was rapidly closing and all traces of clot had disappeared. There had never been any escape of blood or discharge since the initial attack on the night of Nov. 13th, 1900. The hearing remained unaltered.

The patient has been seen on several occasions since and she remains—it is now some 10 months since the initial attack—perfectly free from the symptoms described. The hearing has improved and is practically normal on both sides, as tested by watch.

Remarks.—The sudden onset of subjective noises referred to the occiput, followed by rapidly increasing pains also referred to the occipital region far away from the ear, occurring in the dead of night, was naturally most alarming, particularly as there had been nothing to direct attention to the mischief in the ears. Though there was quick relief from the excruciating pain with the escape of blood from the ear, the rapid evacuation of bright red blood enough to soak two handkerchiefs, following upon a sensation of something bursting in the head, would necessarily at first give rise to considerable anxiety as to whether there was grave intracranial mischief, aneurysm, softening sarcoma, &c. The normal fundi and the rapid recovery to perfect health without subsequent hæmorrhage or other discharge from the ear would exclude such grave mischief. The condition of the urine (with that of the optic discs) and the menstrual history would, respectively, serve to exclude renal trouble or the possibility of vicarious menstruation. The patient, who was of florid type, was at the time of the attack in excellent health after a three months' holiday, and there was nothing to suggest unusual anæmia as a possible cause for the hæmorrhage. The nasal and naso-pharyngeal condition, only brought to notice by my investigation after the onset of the acute hæmorrhage from the ear, serves to explain the mode of origin of the trouble, which had evidently followed long-standing but unsuspected Eustachian catarrh. For some as yet unknown reason acute otitis media appears to have occurred on the first day of symptoms. No history of exposure to cold could be obtained, though this is one of the common causes of this not very common condition, which Roosa first described (McBride). Owing probably to the diminished air pressure within the tympanum, as McBride suggests,[1] consequent upon previously existing Eustachian catarrh, rupture of vessels in the congested mucous lining of the tympanic cavity occurred, thus cutting short the inflammatory process at the stage of vascular engorgement, before inflammation had proceede [illegible] noteworthy that at no pe [illegible] pain and hæmorrhage [illegible] m the middle ear. The [illegible] one of primary hæmo [illegible] the disease, only four hours elapsing between the onset of intense pain and rupture of the tympanic membrane, with evacuation of almost pure blood at first and then serum, being typical.

COCKLES AND TYPHOID FEVER.—At the meeting of the Kingsbridge (Devon) Urban Council held on August 7th the medical officer of health reported a case of typhoid fever which he attributed to eating cockles caught in the estuary of the river. He added that the sewage was carried where the cockles were caught and at his suggestion it was decided to issue handbills immediately warning people of the danger of eating shell-fish caught at the mouth of the river.

EXPERIMENTS WITH THE DANYSZ RAT BACILLUS.

BY E. KLEIN, M.D., F.R.S.,
LECTURER ON GENERAL ANATOMY AND PHYSIOLOGY AT ST. BARTHOLOMEW'S HOSPITAL;

AND

HERBERT WILLIAMS, M.D. LOND., D.P.H. CANTAB.,
MEDICAL OFFICER OF HEALTH OF THE PORT OF LONDON.

THAT the rat has been instrumental in spreading and communicating bubonic plague to the human subject is a statement which has been well established by past experience, and it has therefore become a matter of great importance to all medical officers of health, notably those connected with seaports, to find means by which rats in docks, harbours, sewers, warehouses, &c., could readily and quickly be destroyed on a large scale without any deleterious effects on other animals. As is well known, Danysz maintains that the bacillus which is known as the Danysz rat bacillus achieves this by giving to rats an acute, fatal septicæmic disease which, by ingestion of the bodies of infected and dead animals, rapidly spreads amongst them and consequently readily destroys them or causes them to migrate from the locality. Experiments were instituted both in the laboratory and on a large scale in one of the warehouses of a dock in the Port of London in order to test this alleged destructiveness of the Danysz cultures and of animals dead after injection with such cultures.

TABLE SHOWING THE RESULTS OF EXPERIMENTS OF FEEDING RATS ON MATERIALS MIXED WITH DANYSZ BACILLUS.

Date.	Material used.	How used.	Remarks.	Result.
1901.				
April 23rd	24 tubes of Dr. Danysz's rat virus.	Mixed with bread and laid on floors of warehouse.	April 24th, bread laid down on previous day eaten.	Negative.
,, 26th			,, 27th, ,,	,,
,, 30th			May 1st, ,, ,,	,,
May 3rd			,, 4th, ,, ,,	,,
,, 8th	24 tubes ditto.	,, ,,	May 10th, bread eaten.	,,
,, 11th		,, ,,	,, 13th, ,, ,,	,,
,, 15th		Mixed with water and placed on floor in tins.	May 16th, water not drunk by rats.	,,
,, 16th		Mixed with bread and laid on floors of warehouse.	May 17th, bread eaten.	,,
,, 22nd	12 tubes ditto.	,, ,,	May 24th, bread eaten.	,,
,, 25th		,, ,,	,, 26th, ,,	,,
,, 28th		,, ,,	,, 29th, ,,	,,
,, 31st		,, ,,	June 3rd, ,,	,,
June 14th	Five guinea-pigs dead after subcutaneous injection with Danysz culture.	Laid on floors of warehouse.	June 15th, four guinea-pigs eaten; June 17th, one guinea-pig eaten.	,,
,, 26th	22 mice dead after subcutaneous injection with Danysz culture.	,, ,,	June 27th, nine mice eaten.	,
,, 27th			June 28th, nine mice eaten; June 29th, one mouse eaten; July 1st, three mice eaten.	,,
July 15th	Four guinea-pigs and one rat dead after subcutaneous injection with Danysz virus.	,, ,,	July 16th, three guinea-pigs eaten; July 17th, one guinea-pig eaten; July 19th, the rat was found on this date to be untouched and being putrid was burnt.	,,
,, 17th	Eight guinea-pigs dead after subcutaneous injection with Danysz virus.	,, ,,	July 18th, two guinea-pigs eaten; July 19th, one guinea-pig eaten; July 20th, the remaining five guinea-pigs were found untouched and full of maggots, they were therefore burnt.*	,,

* July 31st: The warehouse has been visited daily since July 17th and no dead rats have been found August 3rd: The warehouse has been visited with the same result. There is abundant evidence that it is frequented by large numbers of rats; but there is no smell to be observed as there would be if rats had died in any number under the flooring. August 12th: Large numbers of rats in warehouse.

The Danysz bacillus by its morphological and cultural characters belongs to the tribe of virulent coli bacilli. It differs from the typical bacillus coli communis by its great motility, its not coagulating milk or forming indol in broth, and its high degree of virulence on rodents; but by its aspect in surface and plate culture, its formation of gas in shake culture, and its acid production in broth and in litmus milk it is clearly a coli bacillus. When inoculated subcutaneously or intra-peritoneally into rodents it causes death, the rapidity of the fatal issue depending on the amount and virulence of the dose. Gelatine culture and serum culture of recent date act more virulently than those of other media (e.g., broth, agar) and the virulence of the former is greater when the culture is derived from a rodent (guinea-pig, mouse) which has died from the acute disease. As an example of a culture possessing a high degree of virulence the subcutaneous injection of from five to 10 divisions of a Pravaz's syringe of a slightly turbid emulsion of the growth into the groin of a guinea-pig of from 200 to 300 grammes weight should cause death of the animal in between 20 and 46 hours. In this case the subcutaneous tissue of the abdomen is swollen and infiltrated with a gelatinous, sanguineous, fluid densely filled with the bacilli, the infiltration extending generally also into the subcutaneous tissue of the thigh and chest. The viscera are much congested and the blood contains also the bacilli in great numbers. Animals dead after being fed on mice or rats which have been killed by subcutaneous injection of cultures of Danysz bacilli show congestion of the viscera, especially the intestines, the bacillus being found abundantly in the spleen and blood.

The point to be determined was whether, as Danysz maintains, the culture of this bacillus is capable of causing death in a large percentage of rats fed on it. On this point the opinions of various observers differ; while, for instance, Kister and Köttgen of Hamburg[1] to a certain extent confirm Danysz's statement, others, like Krausz,[2] failed to confirm it.

1. *Experiments in the laboratory.*—There is no difficulty in showing the high virulence of the Danysz bacillus for rats, mice, and guinea-pigs if inoculated subcutaneously or intra-peritoneally, but it is different when the material is administered by ingestion. While it is a fact that virulent culture injected subcutaneously in a five-division dose into each of 24 mice caused death of all the animals in between 20 and 48 hours, when administered to other mice by ingestion in large doses it caused death of these animals in three, five, and eight days respectively. But the results were different with rats, for in these the feeding experiments with culture produced death in only 33 per cent. between eight and 14 days. There appeared, however, to be a chance of causing death of a larger percentage of rats by feeding these on rodents dead of the disease after subcutaneous injection. Rats were

---

[2] Ibid., May 30th, 1901, p. 351.

fed on mice which had died in 48 hours after being subcutaneously injected with virulent culture None of these rats became ill or died A number of rats were fed on guinea pigs which had died after inoculation with virulent culture, *and here the percentage of dead rats was certainly* increased Of six rats fed with the material from the guinea-pigs (subcutaneous fluid, peritoneal fluid, and spleen) four died from the disease in 11, 12, 11, and 18 days respectively; and of three rats fed with one whole guinea pig two died from the disease in seven and 11 days respectively. So far the laboratory experiments

2. *Experiments in the warehouse* —The accompanying table *gives the results of* experiments *of feeding on a large scale* carried out in a dock warehouse in the Port of London, instituted by Dr W Collingridge, the late medical officer of health, and continued by the present medical officer of health It ought to be stated in explanation of this table that the 60 tubes of Danysz rat virus used between April 26th and May 31st were culture tubes (on agar) which had been directly obtained from the Pasteur Institute of Paris, and that the guinea pigs, mice, and rat used for the feeding experiments from June 14th to July 17th had all been inoculated subcutaneously in the laboratory with virulent culture of the Danysz bacillus and immediately after death from the typical disease were laid on the floors of the warehouse We would also draw attention to the fact that one rat which had died after subcutaneous injection of the typical disease was offered to the rats in the warehouse but was not touched by them, whereas all the mice and the majority of the guinea pigs were readily eaten by the rats of the warehouse

The table shows that unlike the laboratory experiments those carried out in the warehouse were wholly negative, and therefore the expectation of the medical officers of health of a wholesale destruction of rats by Danysz rat bacillus as a preventive measure against plague cannot be considered from the results of the experiments to be of a promising nature

It should be also stated that several rats that had not become ill after feeding with mice or with guinea pigs or directly with culture were afterwards subjected to subcutaneous inoculation with small doses of virulent culture They promptly became ill and died with the typical disease, thus showing that the susceptibility of the rat to the disease by subcutaneous injection is incomparably higher than by feeding

It should be further stated that all laboratory experiments on rats kept in captivity must be conducted with care, since these animals, according to our experience (confirming that of Krausz), are liable to succumb spontaneously In our experience 25 per cent of the animals die in captivity within the first week or 10 days On the other hand, those that remain alive and well after the first week or fortnight of captivity may be considered fit subjects for the experiment It is possible that the great mortality of the laboratory rats observed by Kister and Köttgen may be due to this fact and not to their having been fed with the Danysz culture

A CASE OF SO-CALLED "FŒTAL (OR CONGENITAL) RICKETS"[1]

By HENRY ASHBY, M.D., F.R.C.P. Lond.,

PHYSICIAN TO THE MANCHESTER CHILDREN'S HOSPITAL.

THERE can be no doubt that many of the cases reported in past times as "congenital rickets" were, as a matter of fact, not rickets at all, but achondroplasia or, in other words, chondrodystrophia fœtalis In many of such cases at least the superficial likeness to rickets is great, the long bones are stunted and bent and the epiphyses enlarged Stoeltzner has recently examined a fœtus with a condition which he calls "fœtal myxœdema"., it appears from his description that it resembled rickets, and though the myxœdema seems doubtful it certainly was not rickets It seems certain, also, that there are various pathological processes which may take place during intra uterine life which produce deformities and stunting of the bones quite apart from rickets

In looking over the recent literature of the subject the cases which most resembled fœtal rickets that I can find are two reported by Osgood Mason[2] and Townsend.[3] Both of the patients in these instances died when a few days old, and unfortunately no post-mortem examinations were obtained In each case there were imperfectly calcified bones, both the cranial bones and long bones; the ribs were beaded and bent, the bones of the limbs were curved, the curvature being curiously like the curves produced in acquired rickets, and the epiphyses were enlarged and several fractures were present It is certain in these cases that there was a condition of "osteogenesis imperfecta" with a proliferation of the cartilage at the epiphyses In one of the cases the mother had suffered privation during pregnancy, in the other she had been well fed and cared for.

The following case clearly resembles the two just related and presumably was of the same nature The mother was 46 years of age and the infant in question was her fourteenth child The other children were strong and healthy with the exception of two who had died in infancy from some wasting disease No history could be obtained of syphilis in the mother or in the other children The mother had suffered from some form of jaundice both before and after the birth of the infant and there had been a good deal of vomiting during the pregnancy The infant was well nourished when he was born, and he took food well When a fortnight old he was brought to the Manchester Children's Hospital and admitted under Mr Joseph Collier as he had sustained various fractures, though there was no history of anything like violence The fractures involved the right humerus and radius, and the left humerus, ulna, and femur were also fractured. It was noted at this time that there was marked cranio-tabes, the occipital and parietal bones especially being in a backward condition as regards calcification The ribs also were abnormally soft, as they bent inwards during inspiration on each side of the sternum, forming the broad shallow grooves on each side so commonly seen in rickets There was slight beading of the ribs but no enlargement of the epiphyses of the long bones or any marked curvature The infant was well nourished and had apparently been born at term He was fed on cow's milk and water, the fractures were put up in splints, the fractured femur being treated by vertical suspension The fractures mended up well but when he was six weeks old the right femur fractured This also repaired well, and the infant apparently throve and was sent out of hospital It was noted that in consequence of the softness of the occipital bone it became very much flattened by the pressure of the head on the pillow when the infant was lying on his back When seen at nine months of age the infant had cut two teeth and was bright and intelligent, without any signs of rickets or deformity of the bones The occipital had a normal shape, the chest wall was well expanded, and there were no enlarged epiphyses

What was the nature of these cases? They can hardly be classed as osteomalacia, as in this disease the patient goes from bad to worse, and it is doubtful if it occurs in infants, though in rare instances it seems to have occurred in children Neither can they be said to be cases of fragilitas ossium—in this disease the bones are simply brittle and there is no tendency to bend. Syphilis produces an osteochondritis or epiphysitis but not, as far as I am aware, a tendency to bend as well as to break In the case I have just narrated I cannot help connecting the condition of the infant's bones with the fact that the mother was 46 years of age, had [illegible] child bearing, and had [illegible] the pregnanc[illegible] the infant of malnutrition except in the bones In connexion with this it is interesting to note that Charrin and Gley[4] claim to have produced congenital rickets in rabbits by inoculating the parents with the toxins of diphtheria and blue pus Certainly the cases *here recorded suggest rickets*, but I think a certain amount of caution is required in asserting they were true rickets in the absence of a post mortem examination and a careful examination of the bones by modern methods Cranio tabes may be present in rickets, but it is present also in premature and in badly nourished infants Slight beading of the ribs and abnormal softness of the ribs may be seen under similar circumstances On the other hand, enlarged epiphyses and fractures with curvatures are much more characteristic of rickets or of some intra-uterine disease.

[4] Comptes Rendus de la Societe de Biologie 10e iii, 200 [illegible] (quoted by Ballantyne)

The experiments and observations of Stoeltzner[5] still further impose caution in coming to a conclusion without having first had an opportunity of a histological examination of the bones. Thus Stoeltzner fed a puppy for eight weeks on a diet consisting of horse-flesh, bacon, and distilled water—a diet which was poor in lime salts. The animal gained in weight and also in length during the experiment, but on the tenth day it was noticed to have a waddling gait and there was swelling of the epiphyses of the bones of the foreleg, and later the ribs became beaded and bent. The bones also became tender (?scurvy). At the examination of the bones after death they were noted to be light in weight and very hyperæmic. Their naked-eye resemblance to rickets was very close. According to Stoeltzner, however, they were found on examination to be not true rickets, but simply spongy or in a condition of osteoporosis (*osteoporöse*). According to this author, an enlargement of the epiphyses, accompanied as it is with softening and swelling of the columnar zone of the cartilage, is not pathognomonic of rickets, as it is present in osteoporosis produced by a deficiency of lime salts in the food, and perhaps also in other conditions. In true rickets, though there is no deficiency of lime salts, the cartilage matrix does not undergo temporary calcification as it does normally; also the osteoid tissue built up by the osteoblasts remains uncalcified. In rickets much preparation is made for calcification, but the tissue formed for some reason or other is in a state unfit for the deposit of lime present in the blood. In osteoporosis comparatively little preparation is made for the deposition of the lime salts, but what osteoid tissue there is formed is completely and perfectly calcified. In rickets there is clearly a pathological state; in osteoporosis there is only a shortage of materials. Mr. F. C. Abbott's case, the post-mortem preparations of which by his courtesy I had the opportunity of seeing at the meeting of the British Medical Association this year, was one of undoubted rickets at the time of death at 14 months of age. There was a history of the deformities being present at birth, but the infant did not come under observation till some time later.

What is really wanted before the question of intra-uterine rickets can be finally settled is a careful pathological examination of an infant of the class in question made shortly after birth.

Manchester.

A CASE OF TYPHOID FEVER WITH RELAPSE; PERFORATION AND OPERATION.

BY G. THORNTON, M.D. EDIN., M.R.C.P. LOND.,
MEDICAL SUPERINTENDENT OF THE CIVIL HOSPITAL, PRETORIA;
AND
HERBERT J. GODWIN, M.B., B.S. DURH.,
M.R.C.S. ENG., L.R.C.P. LOND.,
SURGEON (TEMPORARY) TO THE CIVIL HOSPITAL, PRETORIA.

NOTES BY DR. THORNTON.

THE following case may be of interest in view of the increasing number of cases where recovery has followed an operation for perforation of a typhoid ulcer. Although the patient here referred to died eventually, yet from a surgical point of view a success may fairly be claimed.

A woman, aged 27 years, was admitted into the Civil Hospital, Pretoria, on April 20th, 1901, this being about the twelfth day of an attack of typhoid fever. Rose-coloured spots, an enlarged, palpable spleen, and a more or less typical temperature range were to be observed. The fever pursued a normal course and ended about 14 days later by a rapid fall of the temperature. The temperature remained normal for another 15 days and then a definite relapse with a fresh crop of "spots" developed. Constipation, as is common in typhoid fever in this country, was present during both the first attack and the relapse.

The patient on admission was a feeble, emaciated, and anæmic woman, and during the course of the relapse the emaciation and general weakness became very pronounced. In addition, there were signs of bronchitis and hypostatic congestion of the bases of both lungs. Nevertheless, the patient was of the most optimistic disposition and always said she was "doing very well," so that good hopes were entertained of her recovery. Unfortunately, on the eighteenth day of the relapse perforation occurred. The symptoms pointing to this occurrence were pain of moderate severity, colicky in character and much aggravated by coughing, felt chiefly in the right lower quadrant of the abdomen; a rise of temperature of 3° and quickening of the pulse-rate from 100 to 130; thoracic type of respiration; and total disappearance of the liver dulness even in the posterior axillary line, and this without any distension of the abdomen which remained hollow as it always had been. The patient was seen and examined within an hour of the occurrence of pain in the abdomen. A diagnosis of perforation was made and the aid of my surgical colleague was asked for.

With regard to the symptoms diagnostic of perforation I would venture to point out from the experience of several cases seen within a very few hours of the occurrence of this complication that it is frequently to be observed—(1) that the temperature first rises and does not fall with signs of collapse until some hours later; (2) that perforation may occur in cases where instead of tympanites the surface of the abdomen is quite hollow, and that the occurrence of distension in these cases only follows the onset of the consecutive peritonitis and paralytic distension of the gut; (3) that the absence of liver dulness in the mid-axillary line where there is no tympanites is an almost conclusive proof of the presence of free gas in the abdominal cavity, and that even if there be tympanites the liver dulness, although it may be absent in the mammary and anterior axillary line, is never absent in the mid and posterior axillary line without perforation having occurred; and (4) that in perforation there is usually a marked increase in the rate both of the pulse and the respiration. This and an obviously thoracic type of respiration should suggest perforation in a case of typhoid fever and lead to a careful examination of the abdomen. In the particular case here recorded a marked "crack pot" sound was observed on firm percussion in the eighth interspace in the mid-axillary line—a feature which I have never met with before or seen recorded.

My colleague, Mr. Godwin, deals with the surgical aspect of this case, but I may here draw further attention to the good effect which followed the use of calomel and saline purges freely given for the relief of paralytic distension of the gut which came on about from 30 to 36 hours after the operation. The results of the post-mortem examination showed that death was to be entirely attributed to the effects of the fever leading to marked fatty degeneration of the cardiac muscle and the occurrence of hypostatic pneumonia. From a surgical point of view the operation performed was successful, as the patient lived for eight days after it and the sutured gut was found air-tight and water-tight and there were no signs of peritonitis. Considering that the patient was exhausted by a long illness, being in the third week of a relapse, recovery was hardly to be expected; nevertheless the case presents many features of encouragement and fully warrants the belief that early diagnosis followed by suitable operative measures will lead to many recoveries from an otherwise fatal complication of this disease. Success will, above all, depend on early diagnosis, since operations, performed as they frequently are when the symptoms are not those of perforation only but of peritonitis following perforation, can only lead to failure and to condemnation of a thoroughly sound surgical procedure.

NOTES BY MR. GODWIN.

Taking into consideration the length of the patient's illness and her general weak condition I decided with Dr. Thornton that local anæsthesia would be preferable to giving ether or chloroform.

Operation.—The patient having been prepared in the usual manner the extremities were wrapped in cotton wool and two-thirds of a grain of eucaine were injected into the skin of the abdomen five minutes previously to her entering the theatre, and a hypodermic injection of 10 minims of solution of strychnia was administered. She was placed on a hot-water bed on the table and a nurse held a mask over her face so that nothing was visible to the patient. The incision was made in the middle line between the umbilicus and pubes. No gas escaped on opening the peritoneum. The intestinal coil looked very healthy, there was no lymph or fæcal matter to be seen or smelt and no signs of peritonitis, either local or general, were present. On gently pulling out a few inches of small intestine a dark, highly infected patch was found which was the base of an ulcer formed only of peritoneum and apparently on the point of rupture. The intestines were gently passed on through the fingers and a few inches further up a perforation of the size of a pea was found, from which gas and a little yellowish, watery fluid could be expressed. Both ulcers were situated opposite the attachment of the mesentery, there were no signs of any lymph formation. The hole in the bowel was closed by inverting a portion about one inch long by means of Lembert sutures in the long axis of the bowel. Six sutures were introduced and the surface was sealed with collodion. The ulcer lower down, which was on the point of perforation, was then sutured in a similar manner for safety's sake, four sutures being introduced. No toilet of the peritoneum was made. The abdominal wound was closed with silkworm gut sutures, all layers, including the peritoneum, being taken at once and the dressing was applied. The operation was performed two hours after the onset of the abdominal symptoms. The patient stood it well and showed no signs of pain either during the incision through the abdominal wall or during the handling of the gut. She spoke several times during the operation and said that she felt no pain or discomfort. The pulse kept quite as good during the operation as it was previously to it. One hour after the operation the temperature was normal and the pulse was 100, thready, and thin, but regular. Five minims of solution of strychnia and a quarter of a grain of morphia were given hypodermically. On June 6th (the day after the operation) the temperature was normal and the pulse was from 120 to 130, regular, and fairly full. There was no distension of the abdomen and no flatus was passed. The patient remarked that she felt much better. A rectal injection of four ounces of brandy and milk was given every six hours and 10 minims of solution of strychnia were given hypodermically morning and evening. On the 7th the nurse reported that the patient's cough had been very troublesome during the early part of the morning which caused her a good deal of abdominal pain. At 10 A.M. I found the abdomen distended so I removed the dressings. The wound looked healthy, there was considerable tenderness on pressure all over the abdomen, the liver dulness was still absent, and no flatus had been passed. In consultation with my colleague (Dr. Thornton) we decided to give three grains of calomel with sulphate of magnesia every hour until the bowels were moved. After washing the rectum out with quantities of warm water a fair amount of semi-solid fæces and a good deal of flatus were got rid of. On the 8th the patient had had a fair night. The cough was less troublesome and the abdomen was scarcely at all distended. The long rectal tube was passed and the bowel was washed out with warm water, this brought away a large amount of solid fæces. The bowels acted once naturally in the afternoon and in the evening all distension of the abdomen had disappeared. The patient took her nourishment well by the mouth. From this date up to the time of her death, which took place on June 13th, eight days after the operation, the chief trouble to contend with was the condition of the heart and lungs. The pulse gradually got quicker, rising to from 150 to 160 daily in spite of all treatment and the patient was much disturbed with cough and accumulation of secretions in the bronchi and inability to cough them up.

---

[5] Das Fœtale Myxodem und Die Pseudorachitische Osteoporöse infolge von Kalkarme Fütterung. Beiträge zur Pathologie des Knochenwachsthums.

Necropsy.—A post-mortem examination was made 16 hours after death. On opening the abdomen there were no signs of peritonitis or even fluid in the peritoneal cavity. The omentum was slightly adherent to the incision in the abdominal wall, but there were no adhesions of the coils of the intestines either to each other or to the abdominal wall. The sutured portions of the gut were found to be quite air-tight and water-tight. The ulcer that had perforated was about three feet from the ileo-cæcal valve, several healed ulcers from the first attack and also other fresh ulcers of the relapse were found. On opening the chest a little clear fluid was found in both pleural cavities and also in the pericardial sac. Both lungs showed marked hypostatic pneumonia, nearly the whole of both lower lobes being consolidated. The heart muscle, even to the naked eye, was obviously much degenerated, the wall of the right ventricle being specially affected. The valves were normal.

Remarks.—The results of the post-mortem examination show that as regards the intestinal lesion the operation may be considered quite successful. It will be noticed that no general anæsthetic was given, but an injection of eucaine was made in the line of the incision. The patient felt no pain or discomfort and it is obvious from the critical condition in which all such patients must necessarily be that the giving of a general anæsthetic adds materially to the risk of these operations.

Pretoria.

THE COMPARATIVE VIRULENCE OF THE TUBERCLE BACILLUS FROM HUMAN AND BOVINE SOURCES.

By MAZYCK P. RAVENEL, M.D.,

BACTERIOLOGIST OF THE STATE LIVE STOCK SANITARY BOARD OF PENNSYLVANIA; LECTURER ON BACTERIOLOGY, VETERINARY DEPARTMENT, UNIVERSITY OF PENNSYLVANIA.

(From the Laboratory of the State Live Stock Sanitary Board of Pennsylvania.)

(Concluded from page 35[illegible].)

PART II.—TESTING THE PATHOGENIC POWER OF TUBERCULOUS MATERIAL OF HUMAN AND BOVINE ORIGIN.

IN addition to the study of a number of pure cultures obtained from man and cattle we have examined the pathogenic power of tuberculous material from the two sources, also making a series of inoculations which are as nearly parallel as possible. The results of these tests are shown in Table V. and Table VI. The plan was to inoculate a series of animals with tuberculous tissues rubbed into a smooth suspension and at the same time and with the same material to inoculate a number of guinea-pigs which on their death would furnish material for another series of inoculations parallel with those made directly from the human and bovine tissues. It was believed that the material from guinea-pigs would more nearly represent pure cultures of the respective organisms than would be obtained from the tuberculous organs of man and cattle, and that the two sets of animals would lend themselves to an interesting comparison, besides fulfilling the primary object of comparing the virulence of human and bovine material. The plan was carried out for the bovine material but failed for the human, as all the guinea-pigs died within 48 hours after inoculation. The second series of animals were inoculated with human material from another source and obtained at a later date. The results while not entirely comparable are nevertheless interesting and valuable.

Objections to the use of tuberculous material.—There are several disadvantages in using tuberculous material which were not overlooked in planning this work. 1. It is impossible to give accurate doses, for although our suspensions may be made of an equal opacity, and counts of equal amount [illegible] the same number of bacilli, there is [illegible] hat proportion of these bacilli [illegible] 2. Material from man almost always contains other bacteria. Our knowledge of mixed infections is too scanty to enable us to estimate the part played by the other species in determining the result, whether they inhibit or aid the action of the tubercle bacillus. The same is true of bovine material, although to a less extent, the tuberculous foci being more apt to remain inclosed. On the other hand, infection under natural conditions is always through such mixed material and this method of inoculation approaches in some degree the conditions we meet in practice.

Source of bovine tuberculous material.—The bovine tuberculous material was obtained from a cow six years old which had shown symptoms of tuberculosis for a long time and was finally condemned and killed. At the necropsy the animal showed a generalised involvement of the thoracic cavity with some involvement of the abdominal organs. In the lungs but little tissue approaching normal was found. The pleuræ were studded with small nodules. Many of the tuberculous areas in the lungs had undergone caseation.

(*a*) These animals were inoculated with the tissues of guinea pigs which had died from general tuberculosis due to inoculation with material from a tuberculous cow. This material was the same as that used for the inoculation of the other animals. (*b*) Inoculated from tissues of pig 9842 (*c*) Inoculated from tissues of pig 9844 (*d*) Inoculated from tissues of pig 9705. (*e*) Inoculated from tissues of calf 8049. (*f*) Inoculated from tissues of calf 8050.

The mediastinal glands were enormously enlarged and were caseous Scattered over the peritoneum were many nodules The liver was considerably involved and the portal and mesenteric glands were enlarged and caseous Other abdominal organs showed no microscopic lesions Nodules were taken from the pericardium mediastinal and mesenteric glands, the lung and the pleura. After thorough trituration in a mortar, each part separately, they were mixed, sterile water was added and the whole was strained through cheese cloth With this material a series of animals was inoculated and at the same time a number of guinea pigs These all contracted tuberculosis four dying on the fifteenth day Portions of their organs were prepared in the same way and were used for the inoculation of a second series of animals (See Table V)

Sources of human tuberculous material —This material was obtained from three bodies, the lungs only being used Two of the three were cases of well marked acute miliary tuberculosis the other a case of chronic phthisis , all adults The material *was prepared for injection in the same way as described* for the bovine, the suspension being made as nearly of the same thickness as possible The first series of animals was inoculated with the tissues from one of the cases of acute miliary tuberculosis on August 27th A number of guinea pigs were also inoculated with the object of having their tissues for a second series of inoculations, as with the bovine material, but they all died from septicæmia within 48 hours, preventing the execution of this plan With the exception of the pigs and the calves inoculated with sputum the other animals were inoculated from the two cases mentioned above (See Table V)

Method of inoculation —In all the animals the injection was made into the lung the field of puncture being shaven, washed with soap-and water, next with alcohol and ether and lastly with a 1 in 1000 solution of bichloride of mercury The site of puncture was for *the horses between the eighth* and ninth ribs , for the pigs, sheep, and dogs between the sixth and seventh ribs , and for the cats between the fifth and sixth ribs

The following are condensed post-mortem notes of the animals which were inoculated —

Horses —Two animals were inoculated with bovine material. One died after 54 days, with a loss of 195 pounds , the other was killed after 66 days, having lost 60 pounds In both the disease was mainly in the thoracic cavity In the one inoculated with material direct from the cow both lungs were involved throughout. In the other the tuberculous process was confined to the lung into which the injection was made and was marked only near the site of inoculation Two animals were inoculated with human material Both had to be killed One was entirely normal, not even the point of inoculation being discernible In the other the tuberculous process was confined to an area five cubic centimetres in diameter, with the point of inoculation as a centre

Pigs —Four animals were inoculated with bovine material. All died in an average period after infection of 50¾ days The two which received the bovine material direct lived 68½ days as against 33 days for those inoculated from the guinea pigs In all of them the lungs were the chief seat of the disease all showing an acute miliary tuberculosis of both organs In the two inoculated directly from the cow the abdominal cavity was invaded to a limited extent, tubercle being seen only in the mesenteric glands Six animals were inoculated with human material. Five died and one was killed The average length of life of the two inoculated directly from man was 88½ days , for the three inoculated *with tissues* of other pigs which died the average was 22 days In the first two the lungs were invaded throughout with miliary tubercles and one showed areas of pneumonic character In neither was the abdominal cavity involved Of the four pigs inoculated with material from the other pigs which had succumbed to inoculation with human tissues three presented a diffuse tuberculous pneumonia, rapidly fatal one living only 13 days The remaining animal was normal with the exception of the right lung and pleura. Both visceral and parietal pleuræ were largely covered with nodules from two millimetres to 12 millimetres in diameter, many of them caseous The lung was dense throughout and contained many caseous areas most marked near the surface

Sheep —Two animals were inoculated with bovine material Both died the one inoculated directly with bovine material *in 44 days and the other in 32 days* Both were considerably emaciated and in both the disease was confined almost entirely to the thoracic cavity, the spleen being the only abdominal organ involved, and this only slightly so In both the lungs showed hepatisation, more marked in the one inoculated with the tissue of the guinea pig Two animals were inoculated with human material. Both were killed 202 days after inoculation One was entirely normal with the exception of an area in the right lung five centimetres in diameter at the point of inoculation in the centre of which was a caseous abscess the pus containing many tubercle bacilli The second animal was normal throughout

Dogs —Two animals were inoculated with bovine material The dog which received the bovine material direct became markedly ill much emaciated and died after 184 days The pleural surfaces of both lungs were covered with minute nodules and were almost completely consolidated In the right lung at the point of inoculation was a small abscess 2 5 centimetres in diameter The dog inoculated with tissues [illegible] effect from it and was killed [illegible] found was an abscess cavity [illegible] point of inoculation in the right lung scrapings from the wall of which contained many tubercle bacilli Two animals were inoculated with human material One was killed after 229 days The only evidence of disease was the presence of numerous minute nodules on the pleural surfaces of both lungs and a few on the pericardium The lungs were otherwise normal The second dog began to cough after six weeks, lost flesh rapidly, and died on the sixty third day Both pleuræ contained six ounces of sanguinolent pus The lungs were the seat of an extensive miliary tuberculosis and at the point of inoculation in the right lung was an abscess cavity seven centimetres long by 2 5 millimetres in diameter The abdominal organs were not involved.

Cats —Two animals were inoculated with bovine material Both became rapidly ill one dying in 20 days and the other *in 31 days In both the lungs were the seat of an acute* miliary tuberculosis In the one which received the bovine material direct the spleen contained a number of cheesy areas In the other the mesenteric glands were enlarged and cheesy The more rapid progress of the disease in the latter was probably due to its smaller size and the larger dose Two animals were inoculated with human material One cat died after two days and has not therefore been included in the averages The second was killed after 193 days and was found to be normal throughout Not even the point of inoculation could be determined

Summarising these cases 12 animals were inoculated with bovine material 10 of these died while two survived—the horse and the dog which received the tissues of the guinea pigs 14 animals were inoculated with the human material, of which eight died and six were killed For most of the *animals the tuberculous material* direct from the cow seemed to be the more virulent The sheep and pigs were exceptions to this—the pigs notably so those receiving the tissues of guinea pigs dying in 33 days, as against 68½ days for the others The averages of life after inoculation given in the table as well as the greater mortality, show strikingly the increased potency of the bovine material over that from man. This difference is further brought out by the extent and character of the lesions produced by the one and the other, as shown in the post mortem notes above and in Table VI

Infection of calves with human tuberculous sputum —The results of this experiment are included in Table V , the details which are of considerable interest being supplied here

A calf (6984) aged five weeks weight 108 pounds was inoculated intraperitoneally with 10 cubic centimetres of *sputum from an advanced* case of tuberculosis at the University Hospital on July 29th 1898 The patient from whom the sputum was obtained was a young adult who had been ill for about one and a half years and had been expectorating freely for one year A cavity had been observed in the left lung about eight months before the sputum was obtained Death occurred soon after Beyond some slight elevation of temperature this calf showed no effect whatever from the inoculation On Nov 3rd it was tested with tuberculin but gave no reaction When it was killed on Jan 14th 1899 it weighed 256 pounds an increase of 150 pounds It was in good condition and showed no tuberculous lesions in any part of the body The site of inoculation could not be determined

A calf (8493) aged five weeks weight 131 pounds was inoculated on July 29th 1898 with 10 cubic centimetres of sputum of a patient at the University Hospital This patient was an adult male a miner by occupation He

TABLE VI.—SHOWING COMPARATIVE EXTENT OF LESIONS PRODUCED BY INOCULATION OF HUMAN AND BOV MATERIAL.

	Bovine material direct.	Bovine material passed through guinea-pigs.	Human material direct.	
Horses ...	Extensive disease of thoracic cavity.	Extensive involvement of lungs.	One horse limited involvement one lung. The other was normal throughout.	
Pigs ...	Extensive disease of thoracic cavity.	Extensive disease of thoracic cavity.	Extensive disease of thoracic cavity.	Rapidly fatal; very acute process confined mainly to lungs. Slower process in one, confined to lung and pleura of one side.
Sheep ..	Extensive disease of thoracic cavity.	Extensive disease of thoracic cavity.	Limited involvement of one lung and pleura of same side in one animal. The other normal throughout.	
Dogs ..	Extensive disease of thoracic cavity.	Limited involvement of one lung,	Limited involvement of pleura and pericardium in one animal. In the other extensive disease of thoracic cavity.	
Cats ..	Extensive disease of thoracic cavity and spleen.	Extensive disease of thoracic cavity and mesenteric glands.	Normal throughout.	

had been under treatment for nine months. At this period the apices of both lungs were consolidated. He had a cough for two years, lost flesh, and had one severe hæmorrhage. He expectorated a large amount of muco-purulent sputum. This calf showed an elevation of temperature which continued almost without intermission for three months, reaching as high as 105·8° F. in August and September. On Nov. 3rd it was tested with tuberculin and gave a reaction. It was killed on Jan. 9th, 1899, weighing 265 pounds—an increase in weight of 134 pounds. It was in fair condition. There was a nodule in the peritoneum at the site of inoculation. In the omentum were numerous calcareous nodules of the size of a hazel nut and one softened nodule of the size of a hen's egg, which contained inspissated purulent material, and five smaller ones of the same character. The lungs, liver, and spleen were normal, but on the pleural surface of the diaphragm there was a deposit of fibrin which contained several well-defined nodules. On the abdominal surface of the diaphragm was a small amount of grape formation.

A calf (8049), aged about four weeks, was inoculated on May 16th, 1898, intra-peritoneally, with 10 cubic centimetres of sputum from an advanced case of pulmonary tuberculosis at the University Hospital. The sputum contained many bacilli. Beyond a slight cough, which was noticed in July, it showed no symptoms of discomfort and grew rapidly. It was tested with tuberculin on July 30th and gave good reaction. It was killed on August 1st; its weight was 340 pounds and its condition was good; there was a large amount of fat. On the surface of both lungs and on the pleural surface of the diaphragm was a fibrinous deposit. In the cervical lobe of the right lung a few small nodules were found on section. The mediastinal and bronchial glands were somewhat enlarged. The omentum contained a few nodules, and one, about one inch in diameter, which had undergone softening, the contents being rich in tubercle bacilli. The spleen showed a number of nodules. About one-half of the mesenteric glands were enlarged and showed cheesy degeneration. An emulsion from the centre of the softened nodule in the omentum and from portions of the spleen was made and 20 cubic centimetres injected intra-peritoneally into another calf four weeks old, weight 108 pounds, on August 2nd. Beyond a slight cough, noticed on Oct. 10th, the animal showed no ill-effects from inoculation. It was killed on Jan. 10th, 1899; its condition was good. The omentum was adherent to the peritoneum at the point of inoculation and contained some 10 nodules of about the size of a pea. In every other respect the animal was entirely normal.

A calf (8050), aged four weeks, was inoculated on May 16th, 1898, with sputum from an early case of pulmonary tuberculosis at the University Hospital. The sputum contained a large number of tubercle bacilli. Soon after inoculation the temperature of the calf rose and continued high, with some remissions, until it was killed. Its appearance was bad, the coat was dry and rough and the respiration was rapid. It was tested with tuberculin, but the temperature was too high for results. It was killed on August 1st, weighing 190 pounds. On the surface of both lungs there was a slight deposit of fibrin and on section a number of hemorrhagic areas were observed in both. The mediastinal and bronchial glands were enlarged and congested. The abdominal cavity contained about 12 ounces of bloody serum. The peritoneum was thickly studded over its entire surface with nodules from one millimetre to 12 millimetres in diameter, fibrous in character. In many places these nodules had massed together, forming tumours, some five centimetres in diameter, which were dense and fibrous. The spleen contained many [illegible] both on the surface and throughou [illegible] The whole omentum was thickly stud [illegible] two millimetres to 12 millimetres [illegible] these there were three large masses, [illegible] character, two of which were 15 centi [illegible] y seven centimetres wide, and 12 millim [illegible] e third seven centimetres long, [illegible] centimetres thick. The [illegible] was thickly studded with [illegible] mesentery was thickened [illegible] small size. The appeara [illegible] grape or pearl disease. [illegible] mediastinal glands were enlarged an [illegible] at caseous. 20 cubic centimetres of an emulsion made from these glands, which contained a large number of tubercle bacilli, were injected on August 2nd into the peritoneal cavity of another calf, four weeks old, weight 132 pounds. The animal showed no ill-effects whatever from inoculation and was killed on Jan. 10th, 1899. A careful post-mortem examination showed it to be normal in all respects.

Summarising these cases, four calves of nearly the [illegible] age received intra-peritoneally 10 cubic [illegible] tuberculous sputum from different [illegible] containing a large number of tube [illegible] One showed no ill effect from the injection except a slight rise of temperature, and when killed the necropsy was entirely negative. Of the other three, two had persistent high temperature following the injection, but only one showed marked illness otherwise. Post-mortem examination proved that all had become infected with tuberculosis, the lesions in two being quite extensive. From each of these two a second calf was inoculated intra-peritoneally with an emulsion made from well-developed nodules. In both cases the emulsion was rich in tubercle bacilli and a large dose—20 cubic centimetres—was injected. The result was absolutely nega [illegible] animal and practically so in the other. [illegible] received a much larger number of tube [illegible] emulsion than those injected with the spu [illegible] we are led to conclude that the result in the latter was due to a mixed infection which operated to the advantage of the tubercle bacillus. The attempt to infect calves with human sputum by the digestive tract failed wholly. Two young calves (Table V., Nos 8074 and 8096) were given from 30 cubic centimetres to 60 cubic centimetres of sputum containing many tubercle bacilli on 11 days. Some disturbance of digestion resulted at the time, but when killed no trace o tuberculosis was detected.[1]

---

[1] This experiment was conducted by Dr. W. G. Shaw, to whom all the credit is due.

Indications for further investigation.—In the further elucidation of this question cultures should be isolated from as many cases of primary intestinal tuberculosis as possible, and especially those cases in which there is reason to suspect infection by meat or milk. Having obtained the cultures it may well be asked whether or not we are in a position to determine positively the origin of the offending organisms. Are the differences which have been noted in culture, morphology, and virulence sufficiently marked and persistent to make differentiation possible? This I doubt. In my judgment much more work must be done before we are able to determine the origin of a given culture of the tubercle bacillus by examination of it in cultures. At present we know practically nothing of the influence of the human body on the tubercle bacillus, nor what changes may be induced in its morphology, cultural peculiarities, and virulence by residence in the human tissues, nor what length of time is necessary to induce such changes, if induced at all. In my studies I have, as shown in Table III., recovered the tubercle bacillus, both human and bovine, from horses, dogs, swine, goats, and in one instance had the rare, if not unique, opportunity of recovering the bovine organism from man after accidental inoculation. These recovered cultures have all been carefully compared with the originals, and while some differences have been observed and noted in the remarks following the table, with possibly one exception, they have not been of a marked or distinguishing character. In the case of the man the bacillus remained in his tissues from Jan. 1st to Feb. 27th—58 days. The recovered culture was practically identical with the original. This is, however, a shorter time by a great deal than elapses between intestinal infection in children through food and their death, and does not enable us to draw conclusions as to these cases. Like the culture recovered from animals it indicates that the tubercle bacillus is, as a rule, quite tenacious of its characteristics. We have noted constantly that the bacilli found in scrapings from the various organs of the animals inoculated with bovine cultures have been long and beaded, though the culture used was of the short and unbeaded type. The recovered cultures, however, on blood serum have always resembled the original. In a series of examinations of material coughed up by cows I failed, in every case, to find bacilli of what has been described as the bovine type. In fact, the longest tubercle bacilli I have ever observed, except in old cultures, were seen in some specimens of this material. The virulence of this material was considerably greater than human sputum ordinarily is, though the comparison was not made with accuracy.

Retention of characteristics in culture.—On blood serum with 5 per cent. of glycerine the tubercle bacillus from bovine sources will, as a rule, retain its morphological and cultural characteristics for a long time. Culture H has now been grown for two years (July 6th, 1901) and is of the sixteenth generation. Beyond an increased vegetation no marked change can be detected in it. With a single exception (Culture F) the same may be said of all the cultures isolated. This culture was isolated with some difficulty, and so scant was the growth for six generations that I was several times on the point of abandoning it. Only in the sixth generation was growth enough obtained for experimental inoculation. Considerably more growth took place in the seventh, and the eighth grew luxuriantly, since which all sub-cultures have been abundant. From the eighth generation on serum cultures were made on 5 per cent. glycerine agar, and an abundant growth obtained on this medium in the first transfer. Coincident with this increase of vegetative power came a marked change in the morphology. From being short, thick, and staining evenly, it is now long, more slender than in the early growth and shows marked beading. In other words, from being a typical "bovine" culture, it has during the past ten months so changed that it can now pass as a typical "human" culture. It will be observed, by reference to Table IV., that its pathogenic power for guinea-pigs and rabbits was not as great as is usually found in bovine cultures.

Culture in collodion sacs.—The method of culture in the body of living animals, which has been productive of such brilliant results in the hands of the French, offers much assistance in the solution of the problem before us. It has enabled Nocard[2] to demonstrate the possibility of so modifying the mammalian tubercle bacillus that it becomes like the avian organism in culture and pathogenicity. We are now attempting to modify two feebly virulent human cultures by residence in the peritoneal cavity of cattle. Culture M was kept for seven months in the abdominal cavity of a heifer inclosed in collodion sacs, two sacs being used. On removing the sacs but little multiplication of the bacilli was noted. Cultures were recovered directly from the sacs. In the first transfer the cultures grew more rapidly and abundantly than the original culture, but the morphology of the individual bacilli cannot be said to have changed to a noticeable degree. The virulence was not increased. Rabbits were not killed by subcutaneous inoculation. Guinea-pigs died after an average of 42½ days. A calf *inoculated intra-peritoneally showed no ill-effects* and gave no reaction to tuberculin after seven weeks. Culture Nasua narica (coati) of Dr. Theobald Smith, inclosed in collodion sacs, was kept in the peritoneal cavity of a yearling heifer for 11 months. On removal there was considerable increase in the growth, especially in one sac. Cultures were recovered from the sacs and showed some marked changes, especially in the manner of growth. On both blood serum and glycerine agar the growth was most rapid, at least twice as rapid as usual for this culture. On serum it covered the surface in from seven to 10 days, as a thick, white, moist layer, almost cottony near the water at the bottom. On glycerine agar the growth was more dry and wrinkled, but very rapid. The bacilli stain more evenly and are, on the whole, shorter, though long forms are seen. Guinea-pigs and rabbits inoculated subcutaneously are still living after four months. A calf which received four cubic centimetres of a milky suspension in the jugular vein reacted to tuberculin after 10 weeks. The experiment is being continued, the culture recovered from the capsule having been placed again in the peritoneal cavity of another calf. No conclusions can be drawn as yet, though the indications are that both cultures have become less strictly parasitic rather than more so by the procedure.

AS TO THE INTERPRETATION OF THE RESULTS OF THE EXPERIMENTS.

Accepting it as proven that the bovine tubercle bacillus has, as a rule, considerably greater pathogenic power than the human bacillus for a large majority of experimental animals, how should we interpret this in regard to man? Is it fair to conclude that this increase of virulence will hold good for man also? Until the contrary is proven, or until good reason for believing the contrary is shown, it is, in my judgment, right that this conclusion be held, at least as a working hypothesis. I am aware of the objections to this view that will be raised by some and acknowledge freely that it cannot be accepted as conclusive. Virulence is no doubt a factor which is relative to the subject, and exaltation of virulence for one species does not necessarily prove an increased virulence for other species. Indeed, the reverse is true in some instances.[3] However, it cannot be denied as a general rule that when the virulence of a pathogenic organism is increased for one animal it is increased for all that are naturally susceptible to its action.

The tubercle bacillus is unique in the extent of its pathogenic activity, both by direct experimental inoculation as well as by infection under what may be considered more or less natural conditions. The list of animals in which tuberculosis has been observed in parks and zoological gardens is appalling, the discoveries of Dubard[4] and others showing that not even the cold-blooded animals are exempt from this universal scourge. While it may be said of the tubercle bacillus that in cultures in the laboratory it is unusually tenacious of its characteristics, it is certain that in nature it has a wide range of adaptability as a pathogenic agent. Hence for the tubercle bacillus perhaps more than for any other known microbe we are justified in believing that an exaltation of virulence for practically all experimental animals will hold good in the case of man also.

The question can be determined definitely only by direct inoculation of man. To do this experimentally is of course impossible, consequently we are forced to rely for evidence of this nature on those accidental cases which occur from time to time. It has been my fortune to have three such cases come under [illegible] in each of which the infecting organism was known positively to be of [illegible]

[5] Phila[illegible] Medical Journal, July [illegible], 19[illegible]

Similar cases have been reported by Tscherning[6] and Pfeiffer,[7] the latter ending in general infection and death. To these may be added two cases observed by Dr. M. B. Hartzell[8] of the University of Pennsylvania, though in both absolute proof of the bovine origin of the offending organism is lacking. Both occurred in healthy men employed by one of our large American railways to clean and repair cars used in the transportation of cattle In both a well-developed tuberculosis of the skin followed slight wounds of the back of the hand inflicted by broken timbers. In one case the local disease was soon cured and no further trouble resulted. The other, however, ended fatally after about a year, through the infection becoming generalised, with involvement of the lungs. This patient was a robust man, 44 years old, weighing 175 pounds, with a good family and personal history. Dr Hartzell felt able to exclude with reasonable certainty any other source of infection.

Cases such as these permit us to deny with authority the claim which has been made by certain persons that by long residence in animals of the bovine species the tubercle bacillus becomes so changed as to render it incapable of successful residence in the tissues of man. In all of these instances the bovine bacillus grew and multiplied under conditions known to be most unfavourable to it with the production of characteristic lesions and in two of the seven cases gained access to the internal organs causing death, a result which is unusual when the local lesion is due to infection from human sources While the number of cases is too small to enable us to draw sweeping conclusions the indications are that by this mode of inoculation the pathogenic power of the bovine bacillus is at least as great as that possessed by its human congener

Infection through food.—It will not be necessary here to review at length the reported instances of infection through the digestive tract following the use of food products from tuberculous cattle. Most of these of necessity lack precision and are not absolutely demonstrative, though some of them have, as Nocard has said, "almost the value of an experiment." The well-known observations of Stang,[9] Demme,[10] Gosse,[11] and Ollivier[12] leave little doubt of the power of the bovine tubercle bacillus to infect man through the digestive tract.

The evidence derived from the statistics of tuberculosis on this point is purely circumstantial yet of such strength as to be most convincing The compilations of Dr. Tatham bring out most strikingly the fact that in early life some potent factor is at work in causing tuberculosis. In the Harben Lectures for 1898 Sir Richard Thorne speaks of this as follows: "So, also, if you will compare the rates in Tables A, B, and C (pages 5, 6, and 7), and contrast the reduction of 27 9 per cent. which has taken place, under five years of age, during the last 45 years in all forms of tuberculous disease and that of 66 per cent in phthisis with the corresponding one from tabes mesenterica, which only reached 3 0 per cent., you will see that in considering the latter cause of death we are dealing with a totally different state of affairs. . . The matter, too, assumes a still more serious aspect if we limit ourselves to the first year of life when milk is most largely used as food, for then we find that the reductions in the rate of death from the various forms of tuberculosis, which reduction has been going on at 'all ages' for about half a century, not only disappears but is actually transformed into a large increase, reaching no less than 27 7 per cent This in itself is grave enough, but its significance is still further emphasised when we remember what are the circumstances under which this increase in the rate of death from tabes mesenterica has gone on synchronously with a decrease in that from other forms of tuberculosis" Evidence of a similar nature is given by Dr. G. F. Still[13] of the Hospital for Sick Children, Great Ormond-street, in his analysis of 769 consecutive necropsies of children under 12 years of age, 269 of which showed tuberculous lesions. Of these, 117, or 43 5 per cent., were in children under two years old, while in the first three years of life 56·6 per cent, or more than a half of the total number, occurred From his study of the lesions in these cases Dr. Still believes that in 153, or 56·8 per cent., the respiratory tract was the channel of infection, while in 63, or 23·4 per cent., the alimentary canal was responsible, the remaining 53 cases being uncertain or otherwise accounted for. Accepting these figures as given they indicate strongly that milk, the most largely used food, has a considerable part in the spread of tuberculosis, and justify the conclusion quoted from a report made the Council of the British Medical Associa mortality from tuberculosis in early childhoo ing as it is at other ages in the United Ki , and the opinion that this great prevalence of the disease in childhood is due to infection through the alimentary canal by milk from tuberculous cows appears to be well founded. From Germany come further confirmatory facts. Widerhofer gives an analysis of 418 cases of tuberculosis in children, showing among them 101 with involvement of the intestine. Of these, 43, or 42·5 per cent., were between the ages of two and five years, the period of life when cow's milk forms a large part of the food for children.

CONCLUSIONS.

In view of the foregoing experiments, and of the evidence quoted it seems justifiable to conclude:—

1. That the tubercle bacillus from bovine sources culture fairly constant and persistent pec and morphology by which it tiated from that ordinarily foun

2 That cultures from the tw pathogenic power, affording furt the bovine bacillus being very the human for all species of ex with the possible exception of s ceptible to both.

3 That tuberculous material fr cattle and from man corresponds closely in comparative pathogenic power to pure cultures of the tubercle bacillus from the two sources, all animals tested.

4 That it is a fair assumption from the evidence at ha and in the absence of evidence to the contrary, that t bovine tubercle bacillus has a high degree of pathogen power for man also, which is especially manifest in the earl years of life.

ATYPICAL EMPYEMA IN GENERAL PRACTICE, WITH ILLUSTRATIVE CASES AND CRITICAL NOTES.[1]

By C. C. BAXTER TYRIE, M.B., M.C. EDIN.,
LATE DEMONSTRATOR OF ANATOMY, SURGEONS' HALL, EDINBURGH, AND AT THE YORKSHIRE COLLEGE, VICTORIA UNIVERSITY.

THE very frequency of empyema invests the condition with a special interest to the general practitioner—an interest which is emphasised by its perversity in arising when it is least expected and its vagaries in running courses and achieving results which, to say the least, are disrespectful alike to teachers and text-books. The associated operation which is generally performed by the practitioner himself is not always followed by the expected result. Cases sometimes rapidly recover where we had little hope of such a result or, alas, they sometimes disastrously end where we were confident of a happy result. The following cases illustrate the varying behaviour of pleural effusions and the difficulties incident to their diagnosis and management.

CASE 1.—A boy, aged seven years, with satisfactory family history and a previous record of good health, came under my care in March, 1900. His malady for the first five days presented the usual signs and ran the ordina course of a sharp broncho-pneumonia. Resolution on th right side took place, but fluid appeared in the le pleural sac. On the eighth day an exploratory puncture disclosed some pus. On the tenth day the usual resulted in the withdrawal of half a of which was more suggestive of is origin. An interval of three weeks fo scharge copious and fœtid, the temperature unpleasantly hectic behaviour, the cough paroxysmal, and the expectorati fœtid and purulent The lad's general state was an incomprehensible contradiction to the local condition. He ate well and slept well, and he had put on flesh Washing out the pleural sac has been an abhorrence to me since the time when, as a student, I saw a patient bid a hurried farewell to things mundane while having an empyema cavity swilled out with boric lotion Efficient drainage and the injection of glycerines charged with antiseptics but followed by no beneficial results tempted me to risk washing out. The procedure resulted in paroxysmal cough and the escape of the lotion by the mouth. I desisted and, fortified by a consultant's approval, I returned to my former treatment. The end of another fortnight found things unaltered and I had to thank a careless dressing for the ultimate result One evening, on removal of my morning dressing, the nurse found the tube out and was unable to introduce it Next morning I found the patient to be no worse and I did not re introduce the tube The patient made a rapid and perfect recovery, the cough and expectoration gradually disappeared and in a month he was running out and has enjoyed robust health since

CASE 2.—A man, aged 29 years, came under my care in 1899 He had been taken ill at his work seven weeks previously, his symptom being pain in his abdomen The village barber (an anachronism) attended to him The appearance of a lump in three weeks followed by rupture and discharge of pus made the barber a proud man and the demand for his drawing salve straightway much increased The patient, however, kept getting worse and his relatives thought "that they had better have a common (*sic*) doctor" in case he died. Most practitioners have experience of this procedure I found him a seven stone wreck of a 12-stone man. His appearance and the thin discharge from a sinus in the lumbar region outside the erector spinæ made him the presentment of a man in a far-gone case of sacro-iliac disease Diagnosis at sight and leading questions framed accordingly are bad habits which are easily acquired I concluded that I had to deal with a case of nephritic or perinephritic trouble His urine was albuminous and contained pus, and he had slight cough and dulness over the lower part of the right lung I slit up several radiating sinuses and introduced a tube to the bottom of what I thought was the main channel which ran in towards the kidney The lapse of a few days brought no improvement and I discovered another sinus branching off from the other This ascended up under the ribs to a point just below the inferior angle of the scapula. The introduction of a fine drainage-tube, replaced from time to time by a larger, was followed by encouraging results A fortnight found the sanious discharge replaced by a creamy pus His skin had lost its ominous earthy hue, the night sweats had gone and his appetite had returned His subsequent health has been all that could be desired

CASE 3.—The patient was a boy, aged 10 years, whom I was called upon to attend in June 1900 The lad presented the classical signs of peritonitis The account of the onset the previous history, and the progress of the case led me to believe that I had to deal with an acute tuberculous peritonitis grafted on to one of a chronic character The state of the lungs and the cerebral symptoms pointed strongly to a concomitant general tuberculosis Opening the abdomen could not in the face of things be entertained and my hopeless prognosis was endorsed by a medical brother who was called in in consultation. After a few days the patient's umbilicus protruded and as the swelling evidently contained pus I incised and inserted a tube The patient was relieved and picked up for a few days, but then proceeded to develop numerous subcutaneous abscesses over the head and the trunk There was marked dulness over the lower left lung and a hypodermic puncture revealed the existence of an empyema. His relatives had not been at all pleased with the recurring trouble incident to opening the subcutaneous abscesses, and even if I had felt justified in recommending a formal operation it would assuredly have been met with the familiar "Don't put him to any more pain, doctor One morning while he was under an opiate administered the previous night I plunged a knife between the sixth and seventh ribs into the sac and inserted a tube. A tardy convalescence resulted in his being sent to school out of the way as a nuisance He immediately contracted diphtheria and was removed to the infectious disease hospital where between renal troubles and paralyses he ought to have died but did not

CASE 4.—The history of this case is brief and tragic I was called in recently to see a boy 15 years of age, whom I found suffering from an effusion filling the left pleural sac up to the sixth rib There was a history of three days' illness and the lad's general condition was very fair I purposed seeing him in the evening and making an exploratory puncture, but had scarcely got home when an urgent message recalled me to his bedside. I found him livid and collapsed and with a barely perceptible pulse, and he died five minutes after my arrival. A post mortem puncture established the purulent nature of the effusion.

In recording these cases I have mentioned the outstanding features only and have no doubt omitted many particulars which ought to have been furnished. We learn by our own mistakes and those of others, as witness my erroneous primary diagnoses We often attain an undeserved *kudos*, as was shown by the results of the first three cases We are often visited with unmerited censure, as would assuredly have been my lot had I had with me an exploratory syringe when I first visited the fourth case *Post hoc, propter hoc*, constitutes the average layman's logical horizon in medical matters

In Case 1 the oscillating temperature after the operation is noteworthy, after establishing an external drain in an empyema a normal temperature is usually run There were no physical signs indicating communication between a bronchus and the sac previously to the introduction of fluid The communication was, I think not present *ab initio* The effusion was tuberculous and doubtless resulted from the rupture of a caseous gland in the root of the lung—a very frequent cause of effusion Subsequent progressive changes in the vicinity of the original lesion effected the communication I cannot pretend to e
tube three-quarters of an inch
chest wall should effect such
Case 2 illustrates the dictum t
abscess, may open anywhe
assurance that his pain was confined to the abdomen directs attention to the importance of determining whether pain is indicative of immediate local trouble or is a peripheral manifestion of a more central lesion How often in chest troubles does the patient complain of his abdomen, and this is especially observable in pleural affections The root communications and abdominal distribution of the terminations of the lower intercostal nerves explain this phenomenon. An analysis of Case 3 suggests that the empyema may have been secondary to a subphrenic abscess This view may be dismissed as the pus was sweet throughout, there was no admixture of gas and pus at either the abdominal fistula or the thoracic fistula the mischief was on the left side and the age and previous history negatived the presence of any of the usual hepatic, gastric or enteric antecedents of subphrenic abscess

Case 4 is a forcible reminder of the fact that patients suffering from pleuritic effusions sometimes die suddenly, without warning without apparent cause and when such a catastrophe is least expected "I think you might have told us, doctor," is not a pleasant salutation from the relatives of the deceased The advice of an old teacher, "When there is a possibility of sudden disaster in a case let your prognosis be Delphian in its ambiguity," has been a blessing to me in those cases The approval of relatives and the comments of neighbours, whether they are justified or otherwise affect the general practitioner's success in a way which he cannot ignore and a few words of ante mortem warning far outweigh hours of post mortem explanation Thrombosis in the right heart, propagated pulmonary thrombosis and pulmonary embolism account for a few of these deaths Various theories have been advanced to explain that majority where no satisfactory cause is revealed on post mortem examination. I think that consideration of intra pleural physics and a recognition of the vagal reflexes clear the matter up The fatal syncope is invariably preceded by disturbance of the patient: auto-disturbance as in a fit of coughing or from external causes such as in my own patient where I believe that the ordinary necessary movements incident to chest examination were the cause In cases where the chest has been examined immediately before and the then area of dulness contrasted with the condition during the syncope the sudden and vast increase in the area of dulness is very manifest

The study of intra pleural physics is fraught with weariness and vexation of spirit Authorities agree in nothing except in contradicting each other but from the mass of conflicting statements one may gather the following facts The pressure of intra-pleural effusions may vary from a negative of five to a positive of 19 of mercury. The amount of fluid does not always determine the tension, which may be high in the limited effusion or low in a copious effusion. A thick layer of fluid associated with a very high tension may be present, although there exists *no obstacle* to a uniform diffusion in the sac. Neither gravity nor posture will account for this. A sudden and entire collapse of one lung would seem only to represent an abolition of half the respiratory capacity; it is, however, a much graver misfortune. Displacement of the mediastinum and the factor of "unsatisfied elasticity" of the sound lung which is thus introduced reduce its functional efficiency to one-fourth or one-fifth of the normal dual respiratory capacity.

These premisses warrant, I think, the conclusion that many of these sudden deaths admit of explanation as follows. That untoward disturbance of a patient results in a generalisation through the pleural sac of a previously localised pressure. As a result of the attendant pulmonary collapse a previously impaired respiratory capacity of $\frac{4}{5}$ or $\frac{7}{8}$ is suddenly reduced to $\frac{1}{5}$ in an already debilitated subject. Further, an appreciation of the great sensitiveness of the cardio-inhibitory centre in the medulla and the countless afferent paths from the thorax available for transmission of unauthorised stimuli establishes the absurdity of advancing such anatomical and physiological absurdities as "twisting of the vessels," and so on.

The significance of sudden alterations in pleural effusions and the parts played by adventitious cardio-inhibitory stimuli are shown by the deaths and collapses which are incident and subsequent to opening the sac in operating on empyema, when washing out the pleural cavity, when aspirating, or when simply making a diagnostic puncture.

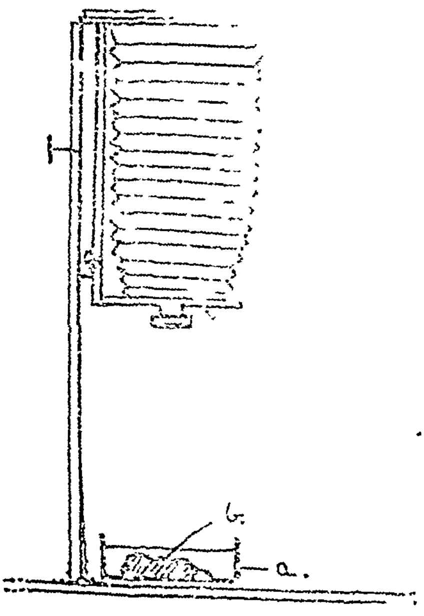
Keighley.

AN IMPROVED METHOD OF PHOTOGRAPHING PATHOLOGICAL SPECIMENS.

BY J. EFFIE PROWSE, M.B., CH.B. GLASG.

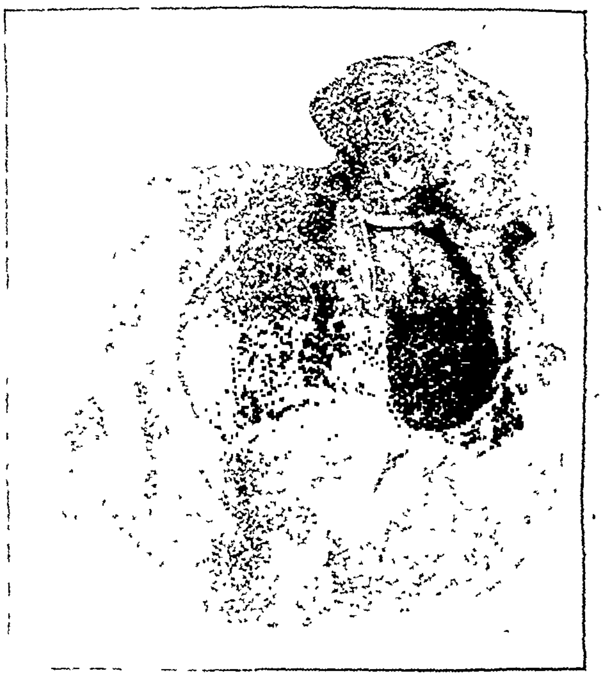
IT *is generally admitted that* to obtain a permanent and accurate record of pathological conditions photography is the most reliable method available to most workers. The results, however, point to much that is unsatisfactory. Specimens, whether removed at operations or post mortem, when viewed on the ground glass appear singularly deformed owing to the patches of light which are always in evidence where there is any moisture. Much difficulty is experienced in getting the object fixed in such a position as it occupied during life. Pinning down to boards, arranging backgrounds, &c., take a considerable time and it is disconcerting to remember that while this is being done, the tissue is probably being irreparably damaged by drying. The finished picture is flat, harsh, and lacking in depth and contour, cystic structures have collapsed, delicate filaments are matted together, cavities are lost, and the original specimen is almost unrecognisable.

FIG. 1.



Showing arrangement of camera.

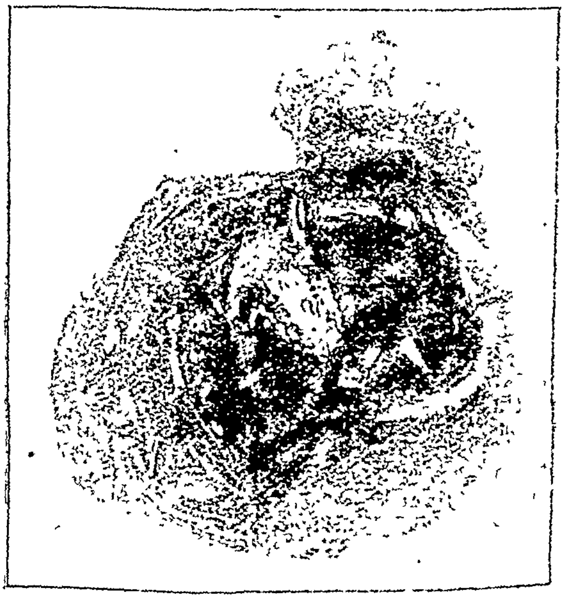
FIG. 2.



From a photograph taken in water.

A very simple method by which all these disadvantages are removed is to photograph all specimens *under water*, but not through glass. The camera is placed in the vertical position, screwed on to an upright, which is attached at right angles to a base board (see Fig. 1). A large glass jar (*a*), with a plain bottom and straight sides, is placed immediately below. In this is placed the specimen (*b*) and water is then added until the former is well covered. Care should be taken that the water is perfectly clean and free from air-bells. A piece of white blotting-paper or a dark piece of wood slipped under the jar forms an excellent background.

FIG. 3.



From a photograph taken in air.

No difficulty will be found in placing the object in a natural position, this is assumed quite mechanically in most cases Cavities expand to their right dimensions, cysts float out in a way quite impossible to imitate when dry, the most delicate lines and hairs are faithfully represented, and the picture when complete shows the specimen as it was originally seen *in situ* with soft delicate outline and marked contrasts

The illustrations speak for themselves The one taken in air (Fig 3) was the best result obtained after several attempts, the one in water (Fig 2) was taken at the first trial

ROYAL HANTS COUNTY HOSPITAL, WINCHESTER

TWO CASES OF GASTRIC ULCER FATAL THROUGH HÆMORRHAGE

(Under the care of Dr H E WINGFIELD and Mr T C LANGDON)

THE mortality from gastric ulcer is difficult to estimate as in all probability many cases are never diagnosed Grünfeldt in 450 post-mortem examinations of patients over 60 years of age found the scars of healed ulcers of the stomach in 92, these figures show a frequency of over 20 per cent in these cases over 60 years of age [1] It is obvious, therefore, that gastric ulcer often escapes diagnosis If we consider only those cases in which a definite diagnosis has been made a high mortality appears which has been given by different authors as between 10 and even 50 per cent The two cases which are recorded below are remarkable in that the presence of the gastric ulcer was overshadowed by other morbid conditions present In the former of the two cases it is not improbable that the gastric hæmorrhage was venous in origin. The latter case demonstrates clearly the importance of necropsies in all obscure cases of death after injury and shows how valueless from a scientific point of view is the verdict "Accidental death" For the notes of the cases we are indebted to Dr T W Letchworth, house physician

CASE 1 —A man aged 45 years, was admitted into the Royal Hants County Hospital on May 5th 1901, complaining of shortness of breath and swelling of the feet On a previous occasion he had been treated for aortic incompetence for several months, but he dated his present symptoms from Christmas 1900 He had been obliged to leave off work a month before admission. He had been a heavy drinker, but had never complained of more gastric pain or discomfort than this and the condition of his circulation would account for On admission he was deeply cyanosed and his face and lips presented a blue and bloated appearance There was œdema of the feet and legs The area of cardiac dulness was increased on either side of the sternum and the apex beat was displaced outwards and downwards There was a double murmur over the aortic area and there was a systolic murmur at the apex conducted into the axilla. The pulse was rapid, irregular, and collapsing and flushing of the forehead with each systole was very marked The liver dulness was slightly increased A diagnosis of aortic regurgitation with secondary mitral regurgitation was made The urine was scanty, of high specific gravity, and loaded with albumin He was bled with temporary relief on several occasions He started to develop ascites about the beginning of June and during the last few days of his life there was evidence of fluid at both bases rapidly increasing in amount. On the morning of June 16th he suddenly vomited about two pints of blood, he vomited blood again twice In all about six pints were brought up, and he died within four hours, evidently from hæmorrhage

Necropsy —At the post-mortem examination the body was found to be œdematous and very pale A large amount of fluid was present in the abdomen and both pleuræ The heart weighed 22 ounces Both ventricles were dilated and hypertrophied. The aortic valves were contracted and were covered with calcareous masses being practically functionless as valves The aorta was very atheromatous The mitral valve was thickened and incompetent The stomach was full of blood On the posterior wall near the lesser curvature and the pylorus, there was an ulcer of the size of a shilling which had penetrated the whole thickness of the stomach wall, which was here adherent to the pancreas behind. Its edges were undermined and enormously thickened There were numerous vessels exposed on the floor of the ulcer, but the vessel whence the hæmorrhage had proceeded was not apparent The liver was cirrhotic and the kidneys were cardiac.

CASE 2 —A man, aged 49 years was taken to the hospital on July 1st, having been upset with a cart which he was driving and which fell down an embankment The horse was supposed to have rolled over him He had sustained a Pott's fracture of both ankles and had broken one of his ribs, about the tenth on the left side He also complained of pain in his back 36 hours after admission he suddenly vomited about one pint of blood On inquiry it was ascertained that he had frequently suffered from pain in the back and epigastrium, especially after meals, had vomited often, and had brought up altered blood The day before the accident he had been laid up with pain and vomiting Copious hæmatemesis continued for about three days and then stopped He died from the effects of hæmorrhage on July 8th

An inquest was held The coroner refused to order a post-mortem examination although he had been informed that it would be essential in order to arrive at a satisfactory conclusion as to the cause of death The house surgeon, in giving evidence stated that death was due to loss of blood but was unable to tell the source. The coroner, having told the jury that in such a case he did not consider a post-mortem examination necessary, advised them to return a verdict of "Accidental death" which was done

Necropsy —With the permission of the relatives a post-mortem examination was then performed. No injuries further than those recognised during life were found The fractured rib had not penetrated the peritoneum and there was no evidence of injury to any viscus There were numerous adhesions about the stomach and great omentum, otherwise all the organs were normal save the stomach Besides the scars of two small ulcers there was on the anterior surface, near the lesser curvature and pylorus, a recent and very superficial ulcer of the size of a sixpenny bit In the centre of this could be seen standing out above the level of the floor of the ulcer a small artery which had been eroded and whence undoubtedly the hæmorrhage had proceeded

Remarks by Dr LETCHWORTH —The peculiarity of the above cases is that in the first the patient seemed when the fatal hæmorrhage occurred, to be actually dying from heart failure due to aortic incompetence and in the second that the hæmorrhage commenced 36 hours after a serious accident involving a crush of the chest and a fractured rib, but in which it seemed impossible to attribute the hæmorrhage in any way to the injury

STATION FAMILY HOSPITAL, CLIFFDEN, MURREE, INDIA

A CASE OF ACUTE VOLVULUS OF THE SIGMOID FLEXURE; LAPAROTOMY WITH FORMATION OF AN ARTIFICIAL ANUS CLOSURE RECOVERY

(Under the care of Lieutenant Colonel H R WHITEHEAD R A M C)

VOLVULUS of the sigmoid flexure is practically the only morbid condition of the large intestine which gives rise to acute intestinal obstruction In most cases simple reduction of the volvulus is insufficient to remedy the obstruction as the volvulus has a great tendency to recur Colotomy is generally needed, at least for a time In the following case the volvulus appears to have persisted owing to the distension of the bowel and to have disappeared as soon as that distension was relieved by emptying the intestine above. Sufficient time appears to have elapsed since the operation to demonstrate the permanence of the relief.

---

[1] THE LANCET, Jan 27th, 1894, p 203

The wife of a sergeant in the Royal Artillery, aged 36 years, was suddenly attacked on Oct. 7th, 1900, at 1 A.M., with most acute abdominal pain and vomiting. For some years the patient had suffered from flatulence, dyspepsia, and colic. She was seen in the morning by Captain F. M. Mangin, R.A.M.C., who was then in charge of Cliffden. She was at this time in great pain, the pain being chiefly referred to the umbilicus. She was vomiting constantly, the vomited matter being the contents of the stomach and mucus. The abdomen was distended and the course of the ascending colon was visible through the abdominal walls. The abdomen was very painful on palpation; the pulse was 100 per minute, thin, and wiry, and the tongue was slightly coated. No purgatives by the mouth were administered, but she was given large enemata. The first enema brought away a small amount of feculent matter from the lower bowel, but no regular action of the bowels took place and no flatus was passed. Captain Mangin diagnosed acute intestinal obstruction and asked Lieutenant-Colonel Whitehead to meet him in consultation on the case. At 3 P.M., when Lieutenant-Colonel Whitehead first saw the patient, she had a typical abdominal expression, her pulse was rapid and wiry, and she was constantly retching and attempting to vomit. The abdomen was acutely painful to touch and was very much distended. Nothing had passed per anum since the night before. The case was evidently one of acute obstruction, and in spite of the short time which had elapsed since the commencement of the attack, her condition was very bad. Lieutenant-Colonel Whitehead recommended immediate operation, and having obtained the patient's consent he proceeded to open the abdomen by a median incision. Captain Mangin rendered valuable assistance and chloroform was administered by Assistant Surgeon Johnstone, I.S.M.D. All aseptic precautions were taken.

The preliminary incision commenced about an inch above the umbilicus and extended in a vertical direction for three inches; this had to be extended at a subsequent stage of the operation. On opening the abdomen a good deal of peritoneal fluid and inflammatory lymph escaped. The cæcum and ascending colon presented in the wound; these were enormously distended. The hand was passed into the abdomen and the course of the large intestine was followed. The upper part of the rectum could be felt empty and collapsed and the sigmoid flexure above full and distended; apparently the gut was bent or kinked on itself at the point of constriction. No constricting band could be made out and the case appeared to be one of this form of volvulus of the sigmoid flexure. As the large intestine was so enormously distended it was feared that any manipulation might rupture the gut and it was determined to evacuate the contents of the bowel. Two stout silk ligatures were passed through the lumen of the gut, just above the cæcum, as in ordinary lumbar colotomy and the bowel was then drawn forward and opened; the sutures were divided and brought out. The gut was pulled as much as possible out of the wound, but owing to the anatomical conditions at this situation this could not be done to any great extent. Lieutenant-Colonel Whitehead then attempted to examine the descending colon in order to untwist the volvulus, but he could not now feel any kink or twist and was afraid that the peritoneal cavity would be much fouled by continuing this procedure. It appeared to him that the relaxation of the intestinal tension by evacuating the contents of the intestine had probably allowed the volvulus to subside, but as he could not be certain that this had occurred, or that the condition might not relapse, he determined to stitch the gut to the skin and to form an artificial anus, which might be closed by a later operation. Before stitching the gut to the skin the abdominal cavity was well flushed by hot boric lotion (2 per cent.) which had been boiled before use.

The patient made an uninterrupted recovery. No signs of peritonitis developed and no rise of temperature occurred after the operation. On Oct. 13th after a simple enema the patient passed a copious formed motion by the natural passage, and almost daily after this a motion was passed per anum after enemata. On the 16th the bowels acted spontaneously, a normal motion being passed. A good deal of feculent matter and intestinal discharge continued to come through the artificial anus. However, from this date the bowels usually acted normally. On Nov. 4th the patient was transferred to the Station Family Hospital, Rawal Pindi; she continued to do well but had occasional attacks of eczema around the artificial anus, although under the influence of resinol ointment the skin kept in very good condition generally. The artificial anus steadily contracted and nearly all feculent matter was passed by the rectum.

On the patient being seen again in January, 1901, the condition was as follows. The patient was in good health and had gained flesh and strength. The artificial anus had contracted very much, the opening in the abdominal walls being now only just large enough to admit a No. 12 catheter. The bowels acted regularly and naturally and nothing in the nature of a spur could be detected. The skin around the fæcal fistula was healthy, but she had suffered from occasional attacks of eczema which were troublesome and painful. The edges of the fistula were cauterised to see if further contraction would follow, but no appreciable change took place. On Feb. 25th the patient was placed under chloroform, the edges of the fistula were pared, and the skin around the edges was freed. The edges of the deep part of the fistula were then brought together by chromic gut sutures, which were cut short and buried, the skin being brought together superficially by salmon-gut sutures. A good deal of vomiting followed the chloroform and on the second day some fæcal discharge forced through the wound and the operation failed to secure direct union, but from this date the opening steadily contracted and on April 15th it had completely healed. When the patient was seen at the end of May the cicatrix was firm and complete recovery had taken place.

Remarks by Lieutenant-Colonel WHITEHEAD.—I have to thank Major B. F. Zimmermann, R.A.M.C., Captin Mangin, R.A.M.C., and Captain T. H. J. C. Goodwin, D.S.O., R.A.M.C., for their care and skill in the after treatment of the case which contributed very materially to the satisfactory result, also Assistant Surgeon Johnstone and Assistant Surgeon Bowder, I.S.M.D.

Reviews and Notices of Books.

Lehmann's Handatlanten: Band VIII., Atlas der äusseren Erkrankungen des Auges. Von Professor O. HAAB in Zürich. Zweite stark vermehrte Auflage, mit 80 farbigen Abbildungen nach Aquarellen von Maler Johann Fink und 7 schwarzen Abbildungen im Text. (*Atlas of the External Diseases of the Eye.* By Professor O. HAAB. Second edition, greatly augmented, with 80 Coloured Illustrations after water-colour drawings by the painter Johann Fink and seven Woodcuts in the text.) Munich: J. F. Lehmann. 1901. Pp. 256. Price 10 marks.

WE have had on several occasions to draw attention to this useful and well-illustrated series of atlases. No less than 18 volumes have been published and several of them have been repeatedly re-edited. The price is reasonable and many of the illustrations are really excellent. The plan adopted is to give in the text which accompanies the plates a description of a group of diseases—as, for example, those of the lacrymal organs. A typical case is then added with a chromo-lithograph of the appearances presented. In the present instance the chromo-lithographs include one of dacryocystitis, a second of lacrymal abscess which has burst without surgical interference, a third showing a lacrymal fistula, and a fourth showing ectasia of the lacrymal sac and incidentally the condition termed "epicanthus." In the text the author lays stress upon the advantage, both as a diagnostic and therapeutic means, of injection of a 0·8 per cent. solution of common salt, but the piston of the syringe must not be made of leather or of asbestos. The diseases with which phlegmonous inflammation of the lacrymal sac is most likely to be confounded are a boil in the immediate neighbourhood of the sac and dental abscess. The treatment succeeds best when the case has not been probed by unskilful hands and when false passages have not been made. When injected by an expert a solution of from 5 to 10 per cent of protargol or a 1 per cent. solution of silver nitrate is very effective Every experienced surgeon will agree with the author in the opinion which he expresses that the treatment of stenosis of the lacrymal passages by means of sounds should only be undertaken by those who are familiar with ophthalmic work, for it presents great difficulties, and more harm than good is often done by incautious sounding The mucous membrane is very tender, the passages are long and tortuous, and the liability to makes false passages is very great It is always painful to the patient, and the pain is not removed even by the previous injection of a 5 per cent. solution of cocaine The author thinks the retention of a sound in the duct after slitting up the canaliculus of doubtful efficacy and prefers excision of the sac He makes a kind of apology for holding these views but there can be no doubt that they are sound Other drawings exhibit the chief affections of the lids, one being a papular syphilid , another blepharitis eczematosa, or as it is named in this country, "ciliary blepharitis", and others represent hordeolum , molluscum contagiosum , chalazion , blepharochalasis ; sugillatio palpebræ, or black-eye, as a result of fracture of the base of the skull , dermoid of the conjunctiva , purulent ophthalmia of infants , diphtheric inflammation of the lids , granular lids , ecchymosis conjunctivæ , follicular and papillary trachoma, spring catarrh , and pemphigus Then follow pterygium, marginal eczematous ulcer of the cornea, or, as we term it, "phlyctenular ophthalmia", wounds and burns of the eye , herpes zoster ophthalmicus , eczema of the head and eyes, various affections of the cornea and sclerotic iritis and it, consequences , affections of the lens , sarcoma of the globe , strabismus , and there are still some others It will be observed that the list is tolerably complete. The atlas is published at a very moderate price and will be very useful to students and to practitioners who have rarely the opportunity of seeing diseases of the eye in the living subject

---

A Practical Treatise on Medical Diagnosis for Students and Physicians By JOHN H MUSSER, M D , Professor of Clinical Medicine in the University of Pennsylvania , Physician to the Philadelphia and the Presbyterian Hospitals, &c. Fourth edition. 250 Woodcuts 49 Coloured Plates London Henry Kimpton. 1901 Pp 1118 Price 28*s*

THE purpose of the author in writing this work has been to deal with the whole subject of diagnosis in its present state of development in clear language and with abundant illustration Dr Musser may be congratulated upon the outcome of his labours A most valuable text book is the result, containing a vast amount of information set forth in a manner to which no exception can be taken The practitioner is thus afforded a work of reference upon which he can rely and the facts and principles are presented so as to give to the undergraduate and post graduate student a rational grasp and practical knowledge of this fundamental part of the science and art of medicine The book is divided into two parts, the first dealing with the "general" and the second with "special diagnosis

The author thoroughly carries out the old dictum "Tota ars medici est in observationibus.' The data to be obtained by inquiry and by observation are detailed at great length, upwards of 400 pages being occupied in the consideration of such matters as the inspection of the face, limbs, skin, conclusions which may be derived from a study of the temperature chart, &c By a careful perusal of these pages a student may hope to become a veritable Sherlock Holmes in the deductions to be arrived at by mere observation of a patient

The chapter on Pain is an excellent disquisition on the recognition and clinical value of this symptom , the points to be remembered in distinguishing between the real severity of the pain and the patient's capabilities of bearing it and the conclusions which may be arrived at from its location, mode of onset, operation, time of occurrence, character, distribution, &c., are stated in plain and explicit terms, and will well repay careful study

A very good description is given of the changes which occur in the hands in the course of various diseases, such as rheumatoid arthritis, nervous affections, &c., and the numerous illustrations aid considerably in the description of the numerous appearances which may be presented

The chapter on the Examination of the Blood is fully up to date The various methods adopted are carefully described and the variations in the corpuscles are commented on and illustrated by numerous plates The remarks on the specific gravity of the blood are scarcely so full as might have been expected, considering the many researches which have been made in this part of the subject

The second part of the book, Special Diagnosis, is also worthy of high praise By means of a plentiful use of ingenious diagrams the physical signs which may be elicited on examination of the different systems of the body are well explained and the student should have no difficulty in at once grasping the meaning which the author intends to convey The diagrams are especially useful in describing the normal and abnormal signs heard on examination of the heart and lungs, and they are also valuable in indicating the deviations from the normal which may be noticed in the palpation and percussion of the abdomen in cases of dilatation of the stomach, ascites, &c. Not only are physical signs thus explained, but symptoms and differential diagnosis are carefully discussed The illustrations are beautifully produced and add to the value of a trustworthy and instructive manual

---

School Hygiene By EDWARD R. SHAW, Professor of the Institute of Pedagogy New York University Teacher's Professional Library London and New York Macmillan and Co 1901 Pp 250 Illustrated Price 4*s* 6*d*

THE method and scope of this work on school hygiene will at once commend themselves to those who take a practical interest in the physical and mental education of young people, since subjects which possess merely academic and scientific interest are relegated to an entirely subordinate position or omitted altogether, while no pains have been spared to supply the fullest and most complete details of the important and essential methods of pedagogy It is mainly from the standpoint of the elementary schoolmaster that Professor Shaw has approached the subject, and although, of course it is to be regretted that matters which exclusively concern higher grade schools fall outside the scope of the work nevertheless from the point of view of higher education, this omission is not of paramount importance, since our own public and high grade schools have little to learn from transatlantic and continental methods except as regards the fundamental principles of hygiene which are common to all varieties of schools , it is these fundamental principles which as above stated, are handled so admirably by Professor Shaw in the volume under review

The opening chapters deal with the subjects of school building, lighting ventilation and sanitation, and what the author has to say on these questions is not with the object of enlightening the architect, the builder, and the plumber, but for the purpose of putting an intelligent schoolmaster in a position to criticise with authority their work as it affects him and his pupils As regards the question of temperature and humidity of the air in schoolrooms Professor Shaw insists that the former should not fall below 60° F and that the latter should be maintained at a level of not less than 50 per cent These figures are of interest because Dr Clement Dukes with the weight of his great authority has suggested that a temperature of from 55° to 60° is the proper one for class rooms, and because when estimations have been made of the humidity of the air in class rooms, it is frequently found to be as low as 30 per cent., and according to the author's personal observations may occasionally fall as low as 20 per cent. Considering the immense importance of the degree of humidity in its effect on the health and comfort of the occupants of a room it is, perhaps, as well to remember that the dry and wet bulb is not a trustworthy instrument for making the determination.

It is difficult to find an opening for criticism in any of the matters dealt with in these early chapters, but perhaps we may be permitted to suggest that if the points of the compass had been appended to the building plans it would not have been without advantage. We would also remark that although *aspect* is admitted to be of importance, in all the plans supplied the class-rooms are arranged completely round the building, so that the light comes indifferently from all quarters; as a rule in modern English schools the class-rooms are carefully grouped in the south and east aspects, leaving when possible the north and west sides for the main hall, kitchens, offices, &c. Again, the hypercritical reader might take exception to a five-foot width of staircase and to the unnecessary allowance of a cloak-room to each class-room, although we believe that this experiment has been made with some degree of success in the Manchester High School for Girls. Further, we cannot altogether agree with the objection which Professor Shaw sees in utilising the basement for a common cloak-room as well as for lavatory accommodation.

What the author has to say on the subject of school furniture will at once command attention. His suggestions as regards design of desk and chair with a view to prevent round shoulders and lateral curvature are admirable in the extreme, but perhaps of less importance in the case of high grade than in that of elementary schools, for in the latter the hygienic home conditions are more liable to favour these physical deformities. It seems almost sacrilege to picture the sixth form of an English public school following in the footsteps of hygienic reform imposed by modern pedagogy, although apart from sentiment it might not be difficult to make out a satisfactory case for improvement. On the question of handwriting Professor Shaw gives rein to a very severe criticism of the methods at present in vogue. He condemns in unequivocal terms the Spencerian script and suggests reforms in the method of teaching and of holding the pen which have so much in their favour that it is possible before long they will be generally adopted. From the bibliography which concludes this admirable little book we cannot understand the omission of G. A. Baginsky's work on "School Hygiene." Previously to the publication of Professor Shaw's own book we had been under the impression that it was about the most important work on the subject.

LIBRARY TABLE.

Typhoid, the Destroyer of Armies, and its Abolition. By LEIGH CANNEY, M.D. Lond. London: Baillière, Tindall, and Cox. 1901. Price 1*s.* net.—King Edward VII., many years ago when Prince of Wales, in opening the proceedings of the International Congress on Hygiene took occasion to put the very pertinent question with reference to preventable diseases that if they were preventable why were they not prevented. Dr. Canney has with great enthusiasm thrown himself into the work of attempting to devise a plan for the abolition, as he believes, of that terrible scourge of armies—typhoid fever. It is the aim and object of his little monograph—after setting forth in a summary fashion the devastations which this fever and some other etiologically allied diseases, such as dysentery and cholera, have caused in all armies of which we have any historical record—to show that these diseases are water-borne and to describe how they can be abolished. Dr. Canney would create a distinct branch of the service with the sole and special object of carrying out his proposals for preventing the recurrence in future of enteric fever, to be known as the Royal Water Corps, and would furnish it with all the necessary transport and appliances for the purpose. Dr. Canney has no difficulty in establishing his first position, for we all know what a dreadful pest this fever has proved itself to be in wars past and present. The long lists of sick grouped together under the heading of "Dangerously ill, enteric where not otherwise stated," which have appeared in the daily newspapers during the war in South Africa would alone suffice to stamp the fact on the memory. It is needless to add, therefore, that Dr. Canney will have everybody's sympathy and best wishes for the success of his scheme. So far, then, all are agreed, but when we come to the discussion of disease-causes and the way to remove them the case is different. Contentious matters arise and the ground becomes much less secure. We are not sure, for example, that it would be universally accepted that contaminated water is so exclusively the source of typhoid fever as he would apparently wish us to believe, although most people would agree with him in thinking that explosive outbreaks of an epidemic nature usually resolve themselves into cases of wholesale water-poisoning, and once this is admitted the importance of the measures advocated by Dr. Canney becomes obvious. There are many who nevertheless hold that the concentration of attention on the search for microbes in the water-supply as the *sole* cause of enteric fever is apt to divert attention from other conditions which may have an important influence in determining outbreaks of the disease. Recent investigations into the sources and methods of infection and pathology of typhoid fever have tended to enlarge and to modify our views in several respects and to introduce some new difficulties in the way of prophylactic hygiene. To enter into these and other points connected with typhoid fever would, however, lead us a long way and we cannot pursue them now. Our readers may have already perused Dr. Canney's letter in the *Standard* of Sept. 10th, 1900, and if they will refer to pages 20, 21, *et seq.*, of the author's present monograph—which only consists of 31 pages altogether and therefore does not take long to read and will repay perusal—they can ascertain for themselves the practical details of his scheme brought up to date of publication. Whether the scheme which Dr. Canney has so ingeniously and industriously worked out is likely to prove a practicable and efficient one under the conditions of war is a matter which requires a good deal of careful consideration to determine. Whether, for example, the estimated amount of mule transport will prove sufficient or whether the demand made on human nature not to drink any water except that supplied by the Royal Water Corps will prove to be too severe and exacting under the conditions of service we cannot say. But it may be possible to apply the words of John Hunter to the matter—namely, not to talk about it but try it.

Lip-reading, or "Hearing by Sight." By Miss G. F. BOULTBEE.—This is a little pamphlet that will be welcome to all those unfortunate people who have become more or less deaf. Miss Boultbee, as the result of long experience, writes in a very sanguine way of the possibilities of lip-reading. Her method is simple and rational, and, as she says, learning to lip-read is a simple process that need not daunt anyone, the only conditions required being the knowledge which a teacher can supply, patience, and perseverance. One useful observation too commonly neglected is made by Miss Boultbee, "when speaking to a deaf person, naturalness and distinction of enunciation are all that is required." Lip-reading has been taught in this country for more than 30 years, and the report for 1900-1901 of the Association for the Oral Instruction of the Deaf and Dumb now before us demonstrates the increasing usefulness of the method and the permanent claim that its teachers have upon public support.

THE LANCET.

LONDON: SATURDAY, AUGUST 17, 1901.

The Employment of Lead Compounds in Pottery.

THE *raison d'être* in regard to the employment of raw lead compounds in the art of glazing pottery has vanished. To our mind Professor THORPE'S latest communication to the Government on this subject is perfectly conclusive and completely justifies this seemingly startling statement. It would be rash, however, to suppose that the vexed question has ended with the results of Professor THORPE'S *exceedingly interesting experiments. Obviously there is no* justice in depriving the potter of the essential materials of his art unless he can be compensated with another material which is equally effective and equally workable. He must have straw wherewith to make his bricks. Fortunately this material has been found in the shape of fritted lead—although not all fritted lead is innocuous; and this latter point is perhaps the most important feature in Professor THORPE'S report which was published last week and presented to the Government.

As is well known, in fritted lead the raw lead (red lead, white lead, or litharge) is fused or fluxed with silica or other material, a definite compound, silicate or boro-silicate of lead, being formed in accordance with the relative proportion of the materials employed. "Fritts" may thus be obtained which may be either soluble or nearly insoluble in acids. The "fritt" insoluble in acids is comparatively innocuous, but "fritts" may be produced which must be rejected as being little less poisonous or soluble than raw lead itself. Any legislation, therefore, to be effectual in preventing lead-poisoning must ensure in the first place that all the lead used in the processes shall be fritted and in the second place that the lead in addition to being merely fritted shall be so fluxed as to produce a "fritt" which is practically insoluble in dilute acids. Professor THORPE'S experiments in the Government Laboratory have made the issue perfectly clear. The members of the trade admit that fritted lead can be substituted for raw lead without prejudicing the industry. Professor THORPE has shown, however, that not all "fritts" are insoluble in acids, and therefore that not all "fritts" are innocuous, while, still more important, he has brought to light the conditions—the facts as to chemical composition which are accessible to manufacturers—determining the solubility of the lead in "fritts." Moreover, these conditions admit of a wide margin as to the proportion of ingredients, for the amount of lead oxide may vary from 15 to 65 per cent. or more without any necessary increase in the solubility of the lead. The compulsory adoption of "fritts" of a standard formula would thus appear to offer a satisfactory solution of the question, and to this intent two special rules were proposed by the Home Office in 1899—(1) that lead shall be fritted; and (2) that the lead shall be properly apportioned with the other materials in the "fritt" so as to secure a "fritt" practically insoluble in acids and comparatively without prejudice to health. The latter rule necessarily involves the adoption of a standard of insolubility, and a maximum of 2 per cent. of soluble lead was suggested as a criterion of safety upon which glazes might be judged.

After nearly a year's consideration the pottery manufacturers proposed an amplification of Rule 1 by the addition of the words "with some silicious substance" after the word "fritted," but this would cast a vagueness of meaning upon the requirements and, as Professor THORPE points out, would allow of raw lead being used with a minimum or even a merely nominal quantity of silica when a "fritt" would be obtained wholly soluble as regards lead and scarcely distinguishable from fused litharge. But while the principle of Rule 1 is accepted by the manufacturers they object *in toto* to Rule 2 which requires that the "fritt" produced must be practically insoluble in acids and that it must conform to a standard of insolubility. This objection is logically absurd. The danger of raw lead, as the manufacturers admit, is its high solubility and the object of fritting is to reduce this solubility to a negligible quantity. It is surely, then, essential that fritting should be placed on a scientific basis, that the ingredients should be properly apportioned in order to attain the highest degree of insolubility possible, and finally that a test should be adopted whereby the insolubility and innocence of the "fritt" can be determined and placed under control. The complaint of English manufacturers is that they are being asked to accept conditions "never before employed by any potters in the world." They would be much more correct in saying "never before enforced upon any potters in the world," for, as Professor THORPE pertinently points out, the standard is reached without the slightest difficulty in large works abroad, and whether it has been attained by voluntary effort or by the pressure of general regulations does not affect the question of practicability. Evidence is being daily gathered that the proportion of highly soluble glazes and "fritts" is becoming smaller as the manufacturers gain greater experience in compounding them.

The truth is that the anti-progressive habit of the average British manufacturer is hard to break. We are convinced that if only a fair trial with an ordinary amount of patience and intelligence be given to the recommendations so aptly drawn up by Professor THORPE neither the art nor the industry will in any way be injured, but rather *their position and dignity will be raised* by removing one of the most terrible stigmas on industrial conditions in modern times. One important omission appears to have been made in this otherwise excellent contribution to the subject—and that is the possibility of lead being dispensed with altogether. In a previous report presented to the Government in 1899 on this subject Professor THORPE, with whom Dr. THOMAS OLIVER was associated, was enthusiastic over the advantages of leadless glazes, expressing "no doubt whatever that leadless glazes of sufficient brilliancy, covering power, and durability, and adapted to all kinds of table, domestic, and sanitary ware, are now within the reach of the manufacturer." The inference is that Professor Thorpe's added experience has led him to the conclusion that lead cannot be omitted without disadvantage either to the industry or to the art.

The Presidential Address to the Members of the British Pharmaceutical Conference.

The British Pharmaceutical Conference met recently at Dublin when the Presidential Address, given by Mr. George Claridge Druce, F.L.S., proved to be of considerable interest to medical men. The President took a somewhat gloomy view of the present condition of British pharmacists, and he stated amongst other things that during the last 40 years the average amount which could be obtained in payment for the goodwill of their businesses had on the whole diminished to the extent of 50 per cent. Pharmacists had therefore several distinct grievances, some of which would be extremely hard to overcome, and he strongly urged members of the conference to unite in facing the difficulties which beset them. No one who is acquainted with life in a country town can doubt that during the last half century the position of a dispensing chemist has by no means improved, and that as a body they have cause for complaint. Forty years ago in a country town there is no doubt that as a rule the dispensing chemist and, perhaps, the bookseller occupied the most prominent positions amongst the tradesmen. The dispensing chemist was, as a rule, better educated than his fellow-townsmen, and so from the first had the advantages which are given by a sound preliminary training; the bookseller was more often a self-educated man, but his constant contact with books and with book-buyers, and the use of his own library, usually made him one of the most interesting men in the town. No one can deny that of late years other tradespeople have to a very great extent taken away the predominant position occupied by the dispensing chemist and the bookseller. This has been greatly due to the general spread of education and somewhat, unfortunately, to the increased and increasing power of money apart from culture.

Mr. Druce gave a *résumé* of the progress made during the last century in those sciences which are of the greatest interest to the dispensing chemist. He sketched briefly the discoveries which have been made in regard to photography, and pointed out that the sale of photographic materials was a branch of business well within the scope of pharmacists, because it deals with the sale of materials where scientific knowledge and accuracy of manipulation should be possessed by the purveyor. A brief review was given of some of the chief discoveries which have been made in pure chemistry, and a number of interesting facts were brought together in regard to the commercial use now made of the by-products of manufactures which had previously been wasted, but which of late years have been more and more utilised. A considerable part of the address was taken up with a review of the progress made in biology, in botany, and in bacteriology; but the most interesting part of the discourse was that dealing with matters more intimately connected with the trade of pharmacy. Mr. Druce pointed out with some emphasis the fact that from a commercial point of view dispensing chemists are, taken as a body, in a much less satisfactory state than was the case during the earlier and middle parts of the last century. He regretted that at the present time there was a falling off in the interest in science which had been shown by pharmacists 20 or 30 years ago, a state of things made evident by the diminution in the number of those who now meet at the conference. This apathy he ascribed in no small part to the loss of income from which the members of the trade are suffering. In regard to the state of the trade at the early part of the last century Mr. Druce thought that it was difficult to form a clear idea as to the position occupied by the chemist and druggist, but that the trade was a many-sided one was not open to doubt. But surely the conditions under which medicine, surgery, and pharmacy were practised during the first half of the last century in London are not mysterious. A great deal of the work fell to the apothecary, and this was the case not only in the City of London but also in the poorer parts of the town and amongst the well-to-do and leisured classes who lived in Soho, in St. James's, and in Mayfair. The physician saw and prescribed for the patients and the active treatment which he ordered was carried out as a rule by the apothecary—in many cases rather a subservient individual who, in the treatment of the upper classes, confined his attention strictly to carrying out the instructions given to him by the physician either by word of mouth or in writing. In those days bleeding was part, and no small part, of the work of an apothecary. It was his function also to cup patients, to supply leeches, to call for the physician's prescription, and, finally, to make up and to deliver the medicine. Many of the apothecaries had open shops and sold other articles of merchandise besides drugs. Of the successors to these apothecaries some became general practitioners as we now know them and some dispensing chemists. The majority of dispensing chemists at the present time doubtless confine their attention to making up prescriptions as ordered and to selling drugs and various other articles more or less intimately connected with pharmacy; though it cannot be denied that here and there may be found gentlemen who add considerable medical and surgical duties to their day's work. It is an unfortunate fact that not only such charlatans as the man Purdue, referred to on page 501, prescribe for and treat the public medically: many respectable dispensing chemists have large counter practices, as we understand they are called. This, in the interests of everybody, should not be.

Mr. Druce said that after the inauguration of an examination by the Pharmaceutical Society an Act of Parliament was passed which gave to the society power to examine and also made the examinations compulsory. As the result of this he believed that the examinations became too purely scientific and that the more practical part of pharmacy was less insisted upon than it should have been. A certain scorn of knowledge of business routine and an undue cultivation of the scientific side of the subject have, therefore, gradually grown up. It is now seriously suggested that the best method to educate a pharmacist would be to send him to college to attend a certain number of compulsory lectures on biology and botany, and then to allow him to pick up a sufficient knowledge of practical pharmacy without any more systematic teaching Mr DRUCE thought that this suggestion, if carried out, *would have a disastrous result, for a man so educated* would be unable to compete with a person brought up in regular business routine in the way in which the draper's apprentice is trained, and in the general struggle for existence the more highly educated pharmacist would be unable to hold his own Mr DRUCE, in enumerating the causes which prevent pharmacists from the profitable carrying on of their businesses, did not omit to mention the position arising out of the fact that it is legal for a company of persons possessing no pharmaceutical knowledge to carry on the business of pharmaceutical chemists He pointed out that when the legislature called the Pharmaceutical Society into being "and insisted that every chemist before commencing business should be qualified" it "out-Gilberted GILBERT by allowing seven people—not one of them qualified—to open a chemist's business and to call themselves chemists" Undoubtedly there is room for reform here

The Case of Concealment of Infants' Bodies at Birmingham.

AMONG other cases dealt with at the assizes recently held in Birmingham was one of great importance from a medico-legal and sanitary point of view, affording as it does another illustration of the defects of our registration system so far as it affects the deaths of infants occurring shortly after birth and the burial of their bodies and of those of still born infants EMMA KNOWLES, aged 32 years, who was *described as an undertaker, pleaded guilty before* Mr Justice PHILLIMORE to committing a nuisance by neglecting to bury the bodies of certain infants entrusted to her for that purpose in May last The case created a great sensation at the time in Birmingham and all over the kingdom, being known as "the Birmingham Scandal" In consequence of complaints having been made of an offensive smell arising from the prisoner's residence the police were informed and the officers on searching the cellar found no fewer than 31 bodies of newly born infants Dr J F CRAIG, *surgeon to the police, was called in* and examined the bodies, most of which were in a very decomposed state. One was that of a deceased infant, but most, if not all, of the others were those of still-births, though it was impossible to give a definite opinion in consequence of their advanced state of decomposition No supposition of foul play was entertained, and the prisoner's excuse was that she, being a widow in very poor circumstances, had taken the money she had received to bury the bodies to buy bread for her starving children She had since May last given up the undertaking business The learned judge observed that the case had its serious aspects It was contrary to public decency and dangerous to public health to treat bodies in this way, and such a practice would facilitate foul play Having regard, however, to her poverty and other circumstances *he would not send her to prison,* but would merely bind her upon her own recognisance to come up for judgment when called upon He trusted that the fact of the conviction would deter other undertakers from doing anything of the kind.

Much credit is due to the Birmingham coroner for the full and searching manner in which the inquest was conducted by him It was stated at the time in a local paper which dealt *severely with the police and mildly with the prisoner* that it was a common practice for undertakers to be asked to take charge in their premises of dead bodies awaiting burial We cannot believe that any respectable undertaker would take upon himself so unpleasant and dangerous a duty in these days, when the providing of public mortuaries is imposed upon all sanitary authorities Moreover, mortuaries open to the public are to be found in all cemeteries Such a scandal as that to which we refer ought to be impossible A glance at the course pursued by those who observe the decencies of life and fulfil the requirements of the law may help to find a remedy *In all cases of infants dying soon after* birth both the birth and death are registered and a burial certificate is given In the case of still-births there is no registration required, but the body is given to an undertaker with a medical certificate of still birth and it is buried in the unconsecrated portion of the cemetery The 18th section of the Births and Deaths Registration Act, 1874, *imposes a penalty of £10 upon anyone who buries or procures to be buried the body of a deceased infant as that of* a still birth, and it is probable that such irregularities are less frequent than they used to be But so long as there is a sliding scale of fees for the burial of deceased infants and of still births so long will there be an inducement to fraud The difference in the two cases varies from half a crown upwards—a very serious consideration to persons who are poor and especially to those who live from hand to mouth Again the sum of half a crown is surely more than is required to pay for the ground occupied by the body of a newly-born infant, whether deceased or stillborn Is it hopeless to ask the Government to bring in legislation requiring the registration of still births? Possibly it would not be wise to propose that undertaking of burials in this country should be by the Government as it is in France and elsewhere on the continent In any case we may reasonably suggest that all burial boards and others having control over churchyards and burial grounds should afford every facility for the reception of the bodies of infants awaiting burial, that the sliding scale should be abolished, and that the burial fee should be reduced to the smallest proportion

Annotations.

"Ne quid nimis"

FACTORY LEGISLATION AND LAUNDRIES.

IT is curious that there should be so many difficulties in respect to factory legislation affecting laundries Considering that laundresses wash precisely those articles which are worn nearest to the skin it would be but natural to anticipate that such an occupation should be subjected to specially strict surveillance We have demonstrated that, in the absence of such control linen after it has been washed, may be contaminated by unhealthy surroundings and brought into contact with the germs of disease. As a result of our revelations[1] on this subject many laundry companies were floated which professed to have established sanitary steam laundries. This helped forward the evolution that has largely assimilated laundry work to factory work. Yet there has always been a great reluctance to apply the same laws to laundries as are applied to factories and workshops. It was said that the Factory Acts required modifications so as to adapt them to the special circumstances of laundries. There is no difference, however, between laundry work and other kinds of repair that require to be done quickly. Of course, the enforcement of the Factory Acts is not a direct guarantee against the contamination of the linen, but the more thoroughly a trade is inspected and regulated the easier it is for the sanitary inspector to complete the work of the factory inspector. Then, again, there is laundry work considered as a domestic industry with which no interference is proposed, but it is precisely in the small cottage or tenement building that linen may be hung out to dry in proximity with cases of infectious disease. It is also in the privacy of a small dwelling that women and children can best be made to elude the law by working more than the number of hours allowed. It seems as if it will be a long time yet before we are able to put on clean linen with any sense of security. Domestic laundries are not inspected at all and even if such inspection were established by law it would be extremely difficult to carry out in practice. So-called model steam and sanitary laundries seem to offer greater security. But of course a far larger quantity of linen is taken to these large establishments and therefore there is a greater chance that some of the linen may be specifically contaminated. Though it is illegal to send contaminated linen to a laundry, this may often be done unwittingly. Both at Marseilles and in Brittany the last cholera epidemic commenced among laundry women. Linen may well be sent to the wash before the presence of infectious disease is discovered. It will be said that boiling kills the germs, but flannels and sanitary woollen underwear should not be put in boiling water. Then the great danger is the manipulating and sorting of dirty linen in the presence of clean linen, the distribution of germs from the one to the other. Laundries ought to be organised on the same principle as are disinfecting stations. On one side should be one set of carts, baskets, and employés for the unwashed linen; on another and well-separated side should be other employés, baskets, and carts for the linen that has been washed. We seem to be a long way from this ideal. But if laundry work in all its phases were assimilated by factory legislation to other trades and occupations, then as these trades were rendered safer and more wholesome by constant inspection and by special regulations, so also might the condition of the laundries be improved. Since the above was written we regret to see that Mr. Ritchie, acting under pressure from the Irish Members and others, moved successfully to omit Clause 103, which contained the special provisions affecting laundries, from the Bill.

THE ARMY MEDICAL SERVICE.

There seems to be a good deal of uncertainty about everything appertaining to the medical service of the army at the present time. The delay in the declaration of the intention of the authorities must, we should imagine, be detrimental to the interests of the public service and also be productive of a good deal of, as it seems to us, inconvenience to all concerned. No one knows for certain, for example, whether Surgeon-General W. Taylor is to be recalled from India to take up the post of Director-General in succession to Surgeon-General J. Jameson, although everybody believes that such will be the case. It is confidently rumoured that Mr. Brodrick has no intention of issuing any definite order on the subject until the meetings of the Departmental Committee now sitting at the War Office have come to an end. If Surgeon-General Taylor is to be the new Director-General, the post he occupies as Surgeon-General and Principal Medical Officer of His Majesty's Forces in India will have to be filled and the selection of his successor will have to be made. That is an appointment which requires a good deal of consideration, for whoever is to fill the post must have had Indian experience and must be an officer of rank and administrative ability with the prospect of sufficient length of service before him to fulfil, or nearly to fulfil, his tour of service in the appointment; for nothing is worse for the service than frequent changes of the head of it. But this is not all; for other changes must occur in the event of Surgeon-General Taylor being suddenly ordered home and possibly having to be replaced by an officer from this country, when the post vacated by the latter will in turn have to be filled and so on. Any sudden order means, therefore, a great deal of trouble, inconvenience, and expense, which would be avoided by giving to the officers concerned some warning beforehand. No one has any right to complain, or ever thinks of complaining, of sudden and urgent orders when necessity occurs, but it becomes a different matter when no such excuse can be urged, and where a process of "hustling" all round could have been avoided. Whoever the new Director-General is to be we cannot understand why some intimation—of a strictly confidential character if need be—should not be made to the head of the medical service, be he merely an acting or temporary head, in order to anticipate those changes which must occur. The appointment of Director-General of the Army Medical Service was for seven years when Surgeon-General Jameson was nominated to fill it. This period was curtailed to five years, but on the late Director-General's retirement he was awarded the rate of pension that he would have received had he served the full time. Still, he was fairly and honestly entitled to occupy the post for two years more than he did, and we have already expressed the feeling—which was not by any means limited merely to his department—that existed, and still exists, as to the circumstances attending his retirement without any recognition of the great and responsible services which he had rendered. The question of the amalgamation of the two medical services —the Royal Army Medical Corps and the Indian Medical Service—has naturally been strongly, but prematurely, taken up and debated in the Indian press; for, as we announced last week, there is, we believe, no intention on the part of the Home Government or of the Government of India to entertain the proposal in this respect of a sub-committee of the Parliamentary Bills Committee of the British Medical Association, nor will any such scheme for amalgamation be considered.

DIPHTHERIA IN COLCHESTER.

At the early part of this year[1] and on one or two previous occasions we called attention to the prevalence of diphtheria in Colchester. The matter was brought into particular prominence because the medical officer of health of Colchester did not believe in the antitoxin treatment of diphtheria, which he termed "bowing the knee to medicinal Baal," while he claimed for his own particular way of dealing with the patients under his charge in the hospital for infectious diseases, that it achieved "results incomparably superior and more satisfactory than those given by the serum treatment." While we admitted that it was as impossible for a sanitary authority as for us or for anybody to dictate to a qualified medical man that he should use a certain remedy for a certain disease, we were constrained to point out that the attitude of the medical officer of health towards accepted medical teaching was very inconvenient. The Colchester

---

[1] The Lancet, August 18th, 1877, p. 240.

[1] The Lancet, Feb. 9th, 1901, p. 426.

Town Council seem now to have arrived at the same conclusion, and not, we think, much too soon. Diphtheria has been present in the city for at least nine months, while there were seven deaths from this cause in May, eight in June, and six in July. In the middle of July the Sanitary Committee resolved unanimously that it was advisable, where antitoxin treatment had not been administered to diphtheria patients before admission to the hospital, that it should be administered on admission. At the end of the month they instructed the town clerk to communicate with Professor G. Sims Woodhead and as a result Dr. Louis Cobbett's services were placed at the disposal of the Town Council as a consulting bacteriologist. Dr. Cobbett lost no time in getting out a report upon the position. In this he attributes the persistent presence of diphtheria in Colchester to spread by personal contact, and points out that isolation of the infected is the only efficacious way of stamping out the disease, and that bacteriological examination must be employed to detect the foci. Dr. Cobbett's report concludes with the following recommendations:—

1. That a practical bacteriologist be appointed to make the necessary examinations and that he be provided with a suitable laboratory and laboratory servant (while this is being arranged swabs might be sent to Cambridge and examined there).

2. That a house and garden be taken, put in charge of a trained nurse and opened as an isolation home for healthy infected persons. (The house might be situated on the outskirts of the town.) All persons admitted to the home should have a prophylactic injection of antitoxin.

3. That a circular letter be sent to all private medical [illegible] of what it is intended to do [illegible] examination for their poorer [illegible] ll as a free supply of anti[illegible] m to submit swabs from all cases which are in the least suspicious, as well as from those which they notify, and from all children and young persons living in houses where these cases occur.

The Town Council of Colchester may not adopt Dr. Cobbett's report entirely, but they will have behind them the solid backing of all the wiser citizens in the town if they follow the majority of his recommendations. It will be a reproach to the community if diphtheria remains longer in their midst to endanger the health and to retard the education of their children.

TWO NEW ROMAN OCULIST SEALS

SOME two years have elapsed since any announcement of the discovery of a Roman oculist seal, but at the February meeting of the French Academy of Inscriptions a description of two new ones was given, one of which is probably the finest specimen of these interesting relics found for many years. They were unearthed during the excavation of a Roman villa near the ancient city of Nasium in the Department of the Meuse. The best preserved seal bears a fourfold inscription and belonged to an oculist named Q. Valerius Flavianus, a personage hitherto unknown. The collyria given by, and the contents of, the four texts, omitting the name which is at the commencement of each one, are as follows: Euodes ad veteres cicatrices ex ti(lia); Dialepidos ad veteres cicatrices ex ti(lia); Diasmyrnes post impetum pituitae ex ovo[1]; Diasmisus ad aspritudines. The first collyrium, Euodes, means simply perfume, but of what it consisted we do not know. There are other collyria of the ingredients of which we are ignorant, such as Anodynum and Diatessarum—i.e., the four ingredients. The cicatrices were affections of the transparent cornea and the pupils and are especially referred to by Pliny, Celsus, and Galen. The second, Dialepidos, used for the same remedial purpose, is protoxide of copper and is frequently stated upon the seals to have been applied for aspritudo or trachoma. These two collyria, however, Flavianus tells us contained another ingredient the first letters of which were "Ti," and it is this which will constitute the special value of this signet, for the word is new. M. Thedenat argues that it stands for "tilia," the lime tree. These oculist seals, after denoting the chief medicament, generally give the vehicle in which it was applied, such as "e lacte muliebri," or, as upon this seal, "ex ovo," and there is no reason to doubt that "ti" indicates a decoction of lime-leaves or limes. For of the tilia or lime, Pliny expressly tells us that decoctions of its leaves were used for the same medical purposes as those of the wild olive, "for inflammation of the eyes," and of the latter he singularly says, "Miscentur oculorum medicamentis et decoctum foliorum et succus oleastri." The ex ti(lia) of the Flavianus seal will correspond to the "miscentur oculorum medicamentis" of Pliny and this reading of the text may be accepted. The third collyrium, Diasmyrnes, myrrh, is very common on the seals, especially as a remedy for post impetum pituitæ (lippitudinis)—that is, after the mucous secretion of ophthalmia. The myrrh here is to be mixed with portions of eggs. The fourth substance, Diasmisus (probably sulphate of iron), is a remedy for the palpebral granulations, or trachoma. It was a favourite ingredient with Roman oculists and is spoken of by Marcellus, Dioscorides, Galen, and Pliny. The possessor of the second seal was one Tiberius Claudius Di[illegible], and it also has an inscription upon the four sides, though only three of these name collyria and not any of them inform us for what form of eye disease they were prescribed. The three given are "Stactum, delachrimatorium," that is oil of myrrh to produce tears, "Diasmyrnes," also myrrh, and "Crocodes anodynum," saffron with an anodyne. The fourth text speaks of a sweet or pleasant collyrium of "T. Claudius Di[illegible] and Solon." Who this medical Solon was is uncertain, but Galen mentions a Solon as the author of several aural remedies. It would be easy, by means of the Corpus of Oculist Seals of 1897, to trace all the maladies for which myrrh and saffron are designated in them, but as we are not certain as to which of them the owner of this seal applied them it is hardly worth doing.

THE EXPOSURE OF FOOD FOR SALE IN THE STREETS

IN busy and crowded thoroughfares the practice of exposing food for sale is open to the greatest objection. The air of such places presents a terrible bacteriological history and the contamination of food sold in open places becomes an easy possibility. Street dust is full of tubercle bacilli from the detestable habit of spitting, it also may contain the microbes of pus, malignant œdema, tetanus, and septicæmia. It is true that the taint deposited on food exposed for sale may be parted in the process of cooking and micro-organisms may be destroyed, although it has been pretty strongly asserted that the cookery of fish in particular has not been effectual in destroying the typhoid bacillus, instances of typhoid fever having been traced to contaminated yet cooked fish. The avidity with which certain foods would appear to absorb noxious odours is well known. Milk is peculiarly liable to take up unpleasant odours and so also is fish. The former is employed when exposed in shallow trays to reduce the smell of paint in a house. Fish cannot be placed in the same [illegible] as coffee or other pungent smelling articles of food as it so rapidly absorbs the odoriferous principle. Busy streets are seldom free from offensive effluvia, and it is reasonable to conclude that these would easily affect many articles of food exposed to them. In our own knowledge quite recently complaint was made that a salmon tasted strongly of creasote. The fishmonger might easily have been charged with selling fish brushed over with a powerfully smelling antiseptic. But it subsequently proved that the Strand (as usual) was "up" and that the stacks of black wooden bricks were giving off a strong naphthalene odour corresponding exactly with the taste of the salmon bought in a Strand shop at the very moment when the bricks were being dumped down on the pavements. This explanation was convincing, but we only quote it as a proof of the liability to contamination of food exposed for sale in the streets under an environment which can seldom be described as hygienic. The fish was probably not injurious to health, but it possessed a decidedly unpleasant taste. Butcher's meat might easily get tainted in the same way. It has been recorded that meat exposed to a current of tobacco smoke has proved powerfully toxic, and this again affords a further illustration of the dangers involved when food is indiscriminately left in contact with air of doubtful purity. It is not desirable that food offered for sale should be exposed to the free influx of air from the streets. If it must be presented to view to attract customers it should be exhibited behind a glass screen, and adequate provision should be made for ventilation with pure air.

---

[1] A seal found in Hungary reads: "Diasmyrnes post impetum ex ovo."

FATAL INTESTINAL HÆMORRHAGE IN PNEUMONIA.

IT is now well recognised that the pneumococcus, the usual pathogenic agent of acute pneumonia, may attack other parts than the lung and give rise to a pneumococcic arthritis, pericarditis, endocarditis, or peritonitis. These conditions have been observed almost exclusively by continental writers. The first case of pneumococcic arthritis observed in this country was published by Dr. Edward J. Cave quite recently in THE LANCET of Jan. 12th, 1901, p. 82 Professor Dieulafoy has described pneumococcic ulcerative gastritis which is now well known in France, but only a few cases of pneumococcic ulceration of the intestine have been reported. At the meeting of the Société Médicale des Hôpitaux of Paris on July 19th Dr. M. Chauffard and Dr. M. F. Rathery related the following case. A man, aged 51 years, addicted to alcohol, was admitted to hospital in a delirious state on March 4th. He had been ill for six days: There were signs of consolidation at the base of the right lung and characteristic pneumonic sputum. The temperature ranged between 102·2° and 104° F. On March 8th a new focus of pneumonia was observed at the base of the left lung. On March 10th, at 5 P.M., the patient passed a considerable quantity of liquid blood. The hæmorrhage continued until 10 or 11 o'clock in spite of all treatment. At least two and a half pints of blood were lost. On the following day the patient was extremely weak and anæmic, the pulse was uncountable, and the temperature had fallen to 100·6°. The hæmorrhage recurred in abundance, the blood flowing from the bed to the floor. Gelatin solution was injected and ice was applied to the abdomen. The hæmorrhage ceased at 3 P.M. In the night it again recurred and nearly a pint of blood was lost. Death took place at 10 A.M. on March 12th. On opening the abdomen the colon was found to be distended and "marbled" with brownish patches which were due to clots seen through its walls. Two-thirds of the right lung were in a state of grey hepatisation. In the left lung the consolidation was less extensive. After washing away the clots in the colon a number of punctiform hæmorrhages were found in the transverse and descending parts. At the splenic flexure were five or six greyish-red, superficial ulcers, from one to two millimetres in diameter, with irregular borders and bases formed of a granular, greyish substance. At the lower part of the descending colon was a larger ulcer, of the size of a large lentil, which was surrounded by numerous small punctiform ulcers. In the rectum was an elongated ulcer. Sections of the ulcers showed great congestion of the mucous membrane and of the submucous tissue. The capillaries were greatly dilated and some were ruptured. The submucous tissue was infiltrated with embryonic cells. The microscopic examination of the intestine showed amidst the microbial flora, especially in the position of the ulcers, numerous diplococci which took Gram's stain. The pneumococcus was cultivated from the lungs and blood. Widal's reaction was absent. Examination of the few recorded cases of intestinal hæmorrhage in pneumonia shows that the hæmorrhage may be slight or profuse and fatal. The ulcers in the present case corresponded both anatomically and clinically to Professor Dieulafoy's "*gastrite ulcéreuse pneumococcique.*"

STREET NOISES.

AS we write there are seven newsvendors visible from our windows. Six of them are yelling "Three o'clock Winner" and one remains silent. No policeman is in sight and if he were it would make no difference. We pointed out in THE LANCET of June 20th, p. 1848, that the police will only act after a personal complaint, and then only if the applicant will promise to attend at the police-court at some date in the more or less immediate future. We also pointed out that the London County Council by-law on the subject of the yelling of newspaper-sellers was made of no effect and we also suggested that persons annoyed by such noises should worry their Council member. We are glad to see a letter in the *Standard* of August 13th from a gentleman resident in Finsbury-circus, mentioning all the points to which we have so often referred in our own columns, and stating that a petition is about to be forwarded to the London County Council on the subject. We say again for about the fiftieth time that there is no reason why newsvendors should shout. The nuisance is absolutely intolerable and must be put down. We may add that the writer of the letter to which we have referred is Mr. Thomas Bowden Green, 1, Finsbury-circus, London, E.C., and that he asks all interested in the matter to communicate with him.

GENERAL PARALYSIS AND SYPHILIS.

DR. W. H. B. STODDART contributes to the July number of the *Journal of Mental Science* a critical digest on the relation of general paralysis to syphilis, a question of great interest in view of the possibilities of the prevention of general paralysis by limiting the spread of syphilis. The fact that (in 1857) Esmarck and Jessen, and subsequently Kjelburg—all Scandinavians—were the first to suggest the syphilitic origin of general paralysis was in itself a strong point in favour of the view, since syphilis was treated in State hospitals in Scandinavia, and therefore the history of previous infection of general paralytics could be easily obtained. It is said that the clinical signs of tertiary syphilis in the form of affections of the skin, eyes, and liver are rare in cases of general paralysis, and, according to Dr. F. W. Mott, the latter affection is more likely to occur in persons who have had syphilis with few or no tertiary manifestations. The relative prevalence of antecedent syphilis in general paralytics has been variously stated by different authors. Thus, Magnan gives the proportion as 4 per cent., Siemerling as 11 per cent. (in women), Kraepelin as 34 per cent., Westphal as 40 per cent. (in women), Binswanger as 50 to 69 per cent , Erb as 52 per cent., Mendel as 75 per cent., Conolly Norman as 80 per cent., and Savage as 80 per cent. Dr. Stoddart gives reasons for thinking that the higher figures (75 to 80 per cent.) represent more closely the real facts of the case, for it is not always easy to determine the occurrence of antecedent syphilis by inquiry into the patient's past history The presence of a soft chancre does not, according to Erb, permit the total exclusion of syphilis, for that author writes ' There are numerous cases of so called soft chancre which are followed later by secondary and tertiary symptoms I have notes of several cases where after apparently gonorrhœa with or without buboes, (urethral chancre ?) secondary symptoms followed The fact that inherited syphilis has been ascertained to be present in nearly all cases of juvenile general paralysis, about 90 of which are known in medical literature, also strongly favours the view of the syphilitic etiology of general paralysis The hypothesis which has been advanced that syphilis is usually acquired during the early or prodromal stages of general paralysis, when the patient is addicted to sexual excess is, says Dr Stoddart, apparently not supported by the observations of Marandon de Montyel[1] who has shown that sexual excess is not such a common symptom of general paralysis as has been supposed, the sexual instinct being exaggerated in but 37 per cent and diminished in 63 per cent of his cases " These numbers agree in a general way with those of Christiani and Oebeke who only differ in placing sexual excess among the causes instead of among the symptoms of general paralysis The relative prevalence of general paralysis in various professions and occupations is such as accords with the view of its syphilitic origin For example, 90 per cent of the cases of general paralysis observed by Professor Krafft Ebing[2] of Vienna were military officers Moreover, Hirschl found but one Roman Catholic priest among his 200 general paralytics and Krafft Ebing had no instance among his 2000 cases of general paralysis of the disease occurring in a Roman Catholic priest Salaris states that there was only one case of general paralysis occurring in Sardinia in a priest during the years 1891 to 1897, and that that priest had certainly had syphilis Dr Stoddart concludes that " syphilis is so frequent an antecedent of general paralysis that the non syphilitic cases (if such exist) may for the present be regarded as a negligible quantity and that hardly anybody runs the risk of getting general paralysis who has not had syphilis

THE RESIDENCE OF A MEDICAL OFFICER OF HEALTH

IT was recorded in THE LANCET of May 11th, p 1373 that the Gelligaer and Rhigos District Council a rapidly developing mining district in Wales having a rateable value of about £100 000 had imposed a condition upon the re appointment of their medical officer of health Dr W W Jones (Merthyr) that he must reside within the parish of Gelligaer, one of the two constituent parishes of the council's area There has been a lengthened controversy between the council and the Local Government Board on the matter It was argued for the medical officer that Merthyr was a natural centre The whole question reached the crisis at a recent meeting of the council when the following letter was read from the Local Government Board —

> 'I am directed by the Local Government Board to acknowledge receipt of your letter of the 5th inst with further reference to the proposal of the Rural District Council of Gelligaer and Rhigos to require their medical officer of health to reside in the parish of Gelligaer The Board considered the representations made by the district council in this matter but they are strongly of opinion that this is not a case in which the district council should insist upon the proposal The geographical features of the district considered in connexion with the railway communication appear to the Board to point to Merthyr as the most convenient spot for the residence of the medical officer of health as from that town he could more easily visit both the outlying portions of the rural district than if he had resided in one of those portions Having regard to this and to the fact that Mr Jones as possessing a D P H has a qualification for the office of medical officer of health beyond those of an ordinary medical practitioner the Board should be glad if the rural district council could see their way to withdrawing the condition they propose to attach to his re appointment

The section of the council who had imposed the condition desired to adjourn the consideration of the letter, as it was patent to them that in consequence of the absence of three members they would be outvoted The chairman however, submitted that the letter was an olive branch held out to the council by the Local Government Board and that therefore it should be acted upon. On a vote of five to four it was decided to suspend the standing orders and subsequently by the same vote the resolution embodying the condition of residence was rescinded and Dr Jones was re appointed unconditionally for one year During the many discussions at the previous meetings considerable excitement has prevailed, which now, we hope, will be abated. One thing should be mentioned. Neither party to the controversy ever had anything but praise for the work and administration of the medical officer whose residential qualification was in question.

PSORIASIS OF THE NAILS RECURRING WITH PREGNANCY

IN the *Scottish Medical and Surgical Journal* for May Dr W E Foggie has described the following curious case A woman aged 28 years, nine years married was seen on August 9th 1899 She was in her sixth pregnancy At the fifth month in this as in every preceding pregnancy except the first, an affection of the nails began with a hot and painful sensation at the ends of the fingers and thumbs Soon the nails began to separate at their free margins and sides and to be raised from their beds by a scaly accumulation Their surfaces became grey lustreless and longitudinally fluted Within a month or two almost every nail had become separated from its bed By October the nails were mostly broken off and the beds were bare except for a small margin of new healthy nail at the root. Some of the growing nails showed considerable transverse irregularities At the beginning of 1900 the nails were almost normal. In April, 1900 when the patient was again in the fifth month of gestation, she again came under observation with the same sensations under the nails In the two latter attacks there were distinct patches of psoriasis on the left elbow, right knee and back of the left hand The affection of the nails in this case corresponds in most of its features with what Mr Hutchinson has described as "psoriasis of the nails'—a condition characterised by accumulation of scales beneath the nails and separation of the nail from its bed which begins at its free edge Various skin affections such as dermatitis herpetiformis urticaria pruritus and eczema have been observed in connexion with pregnancy But psoriasis to say nothing of psoriasis of the nail does not appear to have been described Dr Radcliffe Crocker however, says that psoriasis may clear up during pregnancy

THE RECORDER OF LIVERPOOL AND INSANITARY PROPERTY

THE Recorder of Liverpool in his recent charge to the grand jury at quarter sessions referring to the presentment of the corporation for the demolition of certain insanitary property, remarked that the Liverpool Sanitary Amendment Act 1864 provided means by which the corporation could get rid of those parts called slums such as often abounded in a great city where owing to insanitary conditions disease and wretchedness became rife It was always fitting in such great measures that they should prevent demolition pressing harshly upon the owners of the property, and in deciding as to whether any of the properties recommended for demolition were insanitary those interested in the property should have the opportunity of adducing evidence, if they thought fit, in opposition to the recommendations of the medical officer of health. Evidence was given by the medical officer of health (Dr. E. W. Hope), Dr. William Carter, and Sir Henry Littlejohn (medical officer of health of Edinburgh) as to the utterly insanitary condition of the various properties which had been scheduled. In reply to remarks by objectors to the demolition of their property, Dr. Hope said that the corporation were providing suitable dwellings within reasonable distance from the houses from which the people were to be dispossessed, some in the same streets and others in contiguous streets. The grand jury, of which a section had visited the houses which the owners contended required only structural alterations, reported that nothing in the way of structural alteration could, in their opinion, make them habitable. With the exception of a few tenements which were capable of being rendered sanitary by converting back-to-back tenements into houses with a through draught, all the remaining properties were condemned in very strong terms by the grand jury, who said that they were in a "villainously" unwholesome condition. It doubtless appears harsh to dispossess poor people of their dwellings, but anyone familiar with certain Liverpool slums could not fail to support the recommendations of the medical officer of health to demolish houses, back-to-back in most instances, utterly devoid of ventilation, and being mostly houses in courts upon which the sun never shines.

HYGIENE FOR THE COW.

THE great public interest which has been quickened, if not for the first time really aroused, by the *British* Congress on Tuberculosis, justifies the hope that the medical profession in this country will have behind it the force of public opinion and of public money in its efforts to lessen tuberculosis, and to stamp out the sources from which it spreads. The new and emphatic line of argument taken up by Professor Koch at the Congress has served to heighten the general interest. Roughly speaking, Professor Koch declares that all phthisis arises by inhalation and that a man may eat tuberculous meat and drink tuberculous milk to his heart's content. If this were true, precautions as to the supply of meat and milk would be matters of comparative indifference. At present, however, Professor Koch's position is not proved, and there is a strong consensus of opinion that though the most important steps of all in checking the spread of consumption are those of hygiene which will reduce infection by contact and inhalation, yet milk and meat must be supplied free from the tubercle bacillus if we are thoroughly to combat the disease. As regards the meat-supply Mr. Shirley Murphy's paper in THE LANCET of August 3rd, p. 271, shows how backward we have been in instituting systematic inspections. The letter of a non-medical correspondent, which we have recently received, points out, what is only too familiar to our medical readers, that as regards milk we have in most cases no criterion at all of the purity of source from which it is derived. If fresh air and cleanliness are necessary for human beings to ensure freedom from the attack of tubercle, so, too, are they for cattle. The cow, as well as ourselves, our correspondent contends, needs open-air treatment, whereas too often that most useful animal practically lives in ill-kept byres, dirty cowsheds, and with tuberculous companions. Any railway journey through a country district in England will teach the traveller how little open freedom there is for the cattle. More time in the open air and much more carefully kept accommodation are the great needs of the cow in the country, and in demanding these our correspondent is laying stress upon one weapon in the campaign against tuberculosis which theoretical and unproven considerations must not allow us to undervalue.

THE ANTI-MALARIAL EXPEDITION OF THE LIVERPOOL SCHOOL OF TROPICAL MEDICINE.

THE Liverpool School of Tropical Medicine received a telegram on August 9th from Major Ronald Ross, late I.M.S., stating that he had reached Accra from Lagos and had had a very satisfactory interview with the Governor of the Gold Coast, who promised every assistance to the expedition of the Liverpool School of Tropical Medicine if another delegate were despatched to carry out operations on the Gold Coast. The committee of the school contemplate sending out at an early date an expert to conduct a campaign against the malarial mosquito and malaria on the Gold Coast.

THE NEW POOR-LAW INFIRMARY AT HALIFAX.

THE Halifax Guardians have recently erected, at an expense of some £100,000, a new workhouse hospital. This hospital naturally wants a staff and the guardians are accordingly advertising for a medical officer. This official is to be the responsible medical officer and the head of the medical staff. There will be in addition another visiting physician and a junior medical officer who will be resident. The salary of the principal medical officer is to be £105 per annum, subject to the usual deduction for superannuation, and the appointment is to be subject to the duties being "hereafter defined." So far there appears nothing unusual in the advertisement except the clause referring to the duties being "hereafter defined," a clause which obviously might mean a great deal. But we learn from the local press that the circumstances which led to the appointment being advertised are somewhat peculiar. Dr. T. M. Dolan has been for 30 years the medical officer to the present Halifax workhouse infirmary. For performing the duties of this office—there are 350 beds and there is no question as to the manner in which these duties have been performed—Dr. Dolan receives a salary of £200 per annum. In fact, so impressed were the guardians with Dr. Dolan's worth that they offered him the post of medical officer to the new infirmary without any addition to his salary. Nothing could have been more advantageous. He was to have a free hand, he was to get the whole establishment into working order, he was to have the oversight of 400, instead of as at present 350, beds, and all for nothing. True, at the end of the first year the guardians were going to think about a salary, "if any, and if so what." Dr. Dolan, however, did not see his way to accept this generous offer and hence the advertisement. It may be said: "Why should Dr. Dolan expect an increase of salary for being put in charge of a new and doubtless much improved building?" For one thing, there are 50 more beds than in the present infirmary and, for another thing, the whole work will have to be organised. Another question we may ask is: "Why should the guardians, who pay Dr. Dolan £200 per annum for looking after 350 beds, now only offer their new medical officer £105 for looking after 400 beds?" Dr. Dolan will apparently continue to draw his £200 per annum as medical officer to the workhouse and will also apparently have next to nothing to do, for we do not suppose that the present infirmary at Gibbett-lane will be kept up as well as the infirmary at Salterhebble. As regards the offer to Dr. Dolan we should like to recall to the notice of the Halifax Guardians a passage in Gilbert's delightful play *Engaged*. We mean the passage where the thrifty Cheviot Hill describes the game of "tailoring" to his *fiancée*. "It's a very good game," he says, "you shall be the clever little jobbing tailor, and I'll be the particular customer who brings his own materials to be made up. You shall take my measure, cut out the cloth (real cloth, you know), stitch it together, and try it on; and then I'll find fault like a real customer, and you shall alter it until it fits, and when it fits beautifully that counts one to you." To the ordinary mind it would seem that the guardians might have offered Dr. Dolan the post of medical officer to the new infirmary at a rise, on his present salary, of £100 per annum. But they did not do this, hence the advertisement.

THE DISTRIBUTION OF PLAGUE.

A TELEGRAM from the Governor of Cape Colony, received at the Colonial Office on August 7th, states that for the week ending August 3rd the cases of plague in the Cape Peninsula were as follows: Malays, 1; Europeans, coloured persons, Indians, Chinese, and natives, 0 Corpses found, 0. The deaths were: Malays, 1; Indians, 1; Europeans, coloured persons, Chinese, and natives, 0; total 2. The total cases up to August 3rd were: Europeans, 186; coloured persons, 330; Malays, 62; Indians, 14; Chinese, 1; natives, 142; total, 735 The total deaths up to August 3rd were: Europeans, 64; coloured persons, 175; Malays, 45; Indians, 12; Chinese, 0; natives, 61; total, 357. At Port Elizabeth for the week ending August 3rd the total cases were: natives, 1; no corpses found and no deaths. The total cases to August 3rd were: Europeans, 7; coloured persons, 7; Indians, 2; Chinese, 1; Japanese, 1; natives, 16; total 34. The total deaths to August 3rd were: Europeans, 1; coloured persons, 4; Indians, 1; Chinese, 1; natives, 6; total, 13. The total cases of plague in all other places were: Europeans, 5; coloured persons, 1; natives, 4; total, 10. The total deaths were: Europeans, 1; natives, 1; total, 2. One case in persons under naval and military control occurred in the person of a native from the remount camp. The Port Elizabeth area of infection remains unchanged. In Mauritius, for the week ending August 8th, no cases of plague had occurred. In all Egypt during the week ending August 4th, 6 cases of plague and 1 death from the disease have been reported. Of these, 5 cases occurred among natives and 1 case and 1 death among Europeans (the latter an Italian fisherman without domicile). 3 cases were reported from Zagazig, 2 cases from Port Said, and 1 case and 1 death from Alexandria

THE OVERCROWDING OF ISOLATION HOSPITALS.

UNDER the heading of "Scarlet Fever in South Shields and Jarrow" a correspondent of a South Shields contemporary draws attention to the overcrowding which limited isolation accommodation may at times cause. He mentions more particularly the much-to-be-condemned admission of too many patients—a practice which is liable, as he points out, to lead to more than one child occupying a single bed In our view, such a proceeding as this is open to severe criticism, and we trust that it but very rarely occurs. The fact that children at their own homes often occupy the same bed does not in any way justify such a course in a public hospital to which parents are often persuaded to send their children for the safety of the public health If it be suggested that under any circumstances children are better at a fever hospital than in their own homes we demur altogether to the proposition. It is probable that in the vast majority of cases children in a fever hospital are better housed and looked after than they would be at home, but this is not an invariable rule, and if two children were allowed to occupy one bed such advantage would be considerably curtailed. It seems to us that it is the duty of a medical officer of health, or of a medical superintendent of a fever hospital, to withstand as far as he possibly can any such overcrowding as is here in question A public official is often placed is a very difficult position in this respect with a sanitary authority which does not recognise sufficiently the difficulties and which sees no reason for adequate air-space for each patient. But it is nevertheless incumbent upon the medical officer to take up a firm stand and to point out that any responsibility with regard to overcrowding must rest with the district council or hospital authority; indeed, there might be advantage if medical officers were compelled to report every case of hospital overcrowding to the Local Government Board, in *order that such officers might relieve themselves of responsibility* as far as relief in this sense is practicable. If the sanitary authority compels or persuades a parent to allow his fever-stricken child to be isolated for the public safety that authority is bound to accord to such child every protection against infection of whatever character. The records of the Metropolitan Asylums Board bear ample testimony to the bad effects of overcrowding in the scarlet fever wards, and we believe that the medical superintendents of the Board have made a stand against undue demands upon their space. Briefly stated, overcrowding means increased risk of infection, a chance of less attention in nursing, and finally, enhanced liability to certain complications.

THE SALARY OF A MEDICAL OFFICER IN THE HIGHLANDS AND ISLANDS.

THE following copy of an advertisement from the *Glasgow Herald* of August 7th, 1901, has been sent to us for comment:—

> MEDICAL.—Wanted, by the Parish Council of Lochbroom, a Medical Officer. Salary at the rate of £125 per annum, exclusive of £10 paid by County Council for services as Medical Officer of Health. Comfortable house and garden, which must be occupied by the gentleman appointed and provided at a reasonable rent. Applications, with testimonials, to be lodged with D. S. Ross, Inspector of Poor, on or before the 10th prox.
> Ullapool, 30th July, 1901.

We do not recommend any medical man to apply for this vacancy without making full inquiry from the previous medical officer as to the work to be done. We are informed that the salary is totally inadequate, while out of the pittance a rent has to be returned to the parish.

THE King has appointed Sir Francis R. Cruise, M.D. Dub., Fellow and ex-President of the Royal College of Physicians of Ireland, to be one of the honorary physicians to His Majesty in Ireland, in the room of Dr. William Moore, deceased.

THE next Congress and Exhibition of the Sanitary Institute will be held in Manchester in the second week of September, 1902, under the presidency of the Right Honourable the Earl Egerton of Tatton.

THE report of the Indian Plague Commission is now on its way to India for presentation to the Indian Government. When this has been done it will be laid before Parliament and issued.

MR. JOHN BROWN, L.R.C.P. Irel., has been promoted from Honorary Associate of the Order of the Hospital of St. John of Jerusalem to be Knight of Grace.

ASYLUM REPORTS.

Dundee Royal Asylum (Annual Report for 1900).—The average number of patients resident during the year was 411, comprising 171 males and 240 females. During the year 125 patients were admitted, of whom 55 were males and 70 were females. Of these, three males and 15 females were not first admissions. Dr. James Rorie, the medical superintendent, states in his report that the number of pauper patients admitted during the year has been greater than during the previous year, but still considerably under the average of the years 1895 to 1897. In connexion with the admissions it is noted that while only one patient was received from another asylum, four were admitted from lunatic wards of poorhouses, 13 from the ordinary wards of poorhouses, 17 from the police office, two from prison, and five from the Dundee Royal Infirmary. "The advanced age of many of the patients on admission is also remarkable, three having completed their sixty-seventh year, one the sixty-ninth, one the seventieth, one the seventy-second, two the seventy-fifth, one the seventy-seventh, one the seventy-ninth, one the eightieth, and one the eighty-third year." During the year 43 patients were discharged as recovered, or 10·46 per cent. of the average number resident. The deaths during the year amounted to 38, or 9·24 per cent. as calculated on the same basis. Of the deaths two were due to epilepsy, six to organic dementia, six to general paralysis, six to phthisis and other forms of tuberculosis, and seven to senile decay and heart disease. The rest were due to other causes. In one case death was due to rupture of the heart, a comparatively rare pathological condition. This patient, a female, had been a resident in the asylum for nearly eight years and was to all appearance in her usual state of health. "While sitting on one of the terrace seats she was seen to fall off, was immediately attended to but found to be dead." Post-mortem examination showed rupture of the heart and hæmorrhage into the pericardium. An important event of the year was the erection of buildings for private patients of the better class. The spot chosen was an admirable one affording extensive views of the Tay and the Fife and Perthshire hills and surrounded by woods in the vicinity. The building itself has been fitted with every regard to the comfort and convenience of patients, "and the avoidance of even the appearance of confinement or restraint has been carefully kept in view." Dr. Rorie points out that changes in the staff of nurses and attendants continue to be greater than is desirable. No accident or casualty has occurred during the year that is worthy of notice. The board of directors of the asylum state in their report dated June 17th, 1901, that the new private asylum will soon be ready for occupation. Various legacies, amounting in all to over £700, have been intimated to the institution during the year. A loan of £30,000 has been obtained from the Scottish Equitable Life Assurance Society, the rate of interest payable being 4 per cent. Annuities and donations have been received during the year amounting to £111. The profit on the farm for the year was £215 2*s.* 7*d.* The Commissioner in Lunacy in his report states that the day-rooms, dormitories, and lavatories are maintained in excellent order and were throughout scrupulously clean and that the beds and bedding were in good order. The behaviour of the patients was, except in a very few cases, contented and orderly. "The personal condition of both sexes, and the tidiness of their clothing, were satisfactory. The industrial employment and amusements of the patients receive due attention."

Wonford House Hospital for the Insane, near Exeter (Annual Report for 1900).—The total number of patients under treatment, including voluntary boarders, was 167. The admissions during the year amounted to 34, not including six voluntary boarders. This is an increase of nine certified patients and of two boarders as compared with the previous year. Dr. P. Maury Deas, the medical superintendent, states in his report that of the admissions 11 were cases transferred from other institutions and therefore not hopeful cases as regards the prospect of recovery. Of the new admissions 15 were considered favourable cases as regards recovery, and of these three were discharged as recovered by the end of the year, while eight more have since recovered or are convalescent. The total number of cases discharged as recovered during the year was 11 (four gentlemen and seven ladies). Seven patients were transferred to other institutions. The deaths during the year amounted to four, being a death-rate of 3 per cent. on the average number resident, which is the lowest rate since 1895 One death was due to senile decay, and one each to general paralysis, heart failure and chronic cystitis, and concussion of the brain. Many of the patients in residence are of advanced age. At the end of the year 50 out of a total of 134 patients were upwards of 60 years of age, and of these 16 were between 70 and 80 years, and seven were upwards of 80 years. The Commissioners in Lunacy state in their report that much improvement has taken place since their previous visit in regard to renovation, painting, and re-decorating the wards. The patients were quiet and well behaved with the exception of some of the lady patients who were noisy and rude. The cost of maintenance is £2 2*s.* 11*d.* per head weekly, so that the institution "continues to do really charitable work, and as long as this is the case we hope it will flourish more and more."

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.

A quarterly meeting of the Royal College of Physicians of Edinburgh was held on August 6th, Dr. T. R. Fraser, the President, being in the chair.

The President referred in respectful and feeling terms to the death of Her Imperial Majesty the Empress Frederick of Germany. On the motion of the President it was resolved unanimously to send a telegram of condolence to His Majesty the King in the following terms :—

The Private Secretary of His Majesty the King,
Cowes, Isle of Wight.

Please convey to His Majesty the King the respectful and sincere sympathy of the President and Fellows of the Royal College of Physicians of Edinburgh on the occasion of the sad death of Her Imperial and Royal Highness the Empress Frederick and Princess Royal of Great Britain.

And, further, it was decided to send a telegram of condolence in similar terms to His Majesty's Ambassador at Berlin for presentation to His Imperial Majesty the German Emperor.

Dr. Lewis Campbell Bruce was introduced and took his seat as a Fellow of the College.

Douglas Chalmers Watson, M.B., C.M., M.R.C.P. Edin., was admitted by ballot to the Fellowship of the College.

On a ballot the following candidates were admitted to the Membership of the College after examination. William Edward Home, M.D., C.M. Edin., London; James Burnet, M.B., Ch.B. Edin., Edinburgh; Alexander Goodall, M.D. Edin., Edinburgh; and George Norman Meachen, M.B., B.S. Lond., London.

The Registrar reported that since the last quarterly meeting 67 persons had obtained the Licence of the College by examination.

The Secretary laid on the table the annual statement by the governing board of the School of Medicine of the Royal Colleges in terms of the constitution. The report indicated that the number of classes during the winter session 1900–1901 was 37 and during the summer session of 1901 41, and that the number of students during the winter session was 1160 and during the summer session 1119. The College re-elected the vice-president (Dr. J. Andrew) and Sir John Sibbald, M.D., F.R.C.P. Edin., who retired by rotation as representatives on the governing board of the School of Medicine of the Royal Colleges.

Intimation was made that Dr. G. A. Gibson had, on the nomination of Dr. Alexander Morison, been appointed Morison lecturer for two years, 1901–1902.

Mr. Stuart Macdonald, M.B., C.M., M.R.C.P. Edin., was after examination recognised as a lecturer in pathology, the President conferring on him the certificate of qualification.

A committee of award was appointed in connexion with the Victoria Jubilée Cullen prize. The prize, which was instituted by His Excellency the late Dr. R. H. Gunning, is of the value of £100 and is awarded every four years "for the greatest benefit done to practical medicine." The prize is open to Fellows, Members, and Licentiates of the College. The award will be made in June, 1902.

On behalf of Lady Jenner the President presented to the College a photogravure of Mr. Frank Holl's portrait of the late Sir William Jenner, Bart.

It was agreed unanimously to send a congratulatory address to Professor Virchow on the occasion of the eightieth anniversary of his birthday.

Weston-super-Mare Hospital.—As a result of the recent *fête* held in aid of the funds of this hospital the sum of £570 has been handed over to the institution.

THE BRITISH MEDICAL ASSOCIATION.

MEETING AT CHELTENHAM.

THE GENERAL MEETINGS.

THE THIRD GENERAL MEETING

THE following is the report of the Third General Meeting, at which, as we mentioned in our issue of August 10th the concluding portions of the Report of the Constitution Committee were passed

The first clause discussed was No 16, dealing amongst other matters with the payment of expenses of representatives travelling to attend meetings

Mr R J [illegible] that instead of the words [illegible] the terms should be "first-c[illegible]" But the proposal was withdrawn upon Dr [illegible] WOODCOCK (Manchester) asking how it was possible for medical men from Ireland to cross the Channel in a railway carriage

According to Clause 16 the expenses of representatives were to be defrayed by the Association It was pointed out that this might mean that the Branches were to pay these expenses It was therefore moved by Mr J. S WHITAKER (Yarmouth), seconded by Dr A B RITCHIE (Manchester) and carried that the expenses should be defrayed by the central funds of the Association After various motions had been proposed without success to pay for second-class travelling instead of first, to pay only for third class travelling and not to pay any expenses at all, Clause 16 was then put to the meeting and declared passed as follows —

Annual Meeting, General Business, General and Sectional Scientific, and Representative Meetings

16 That there be held annually, for the transaction of the various affairs of the Association, a general business meeting and general and sectional scientific meetings, all open to all members of the Association and a representative meeting, open only to representatives elected by the divisions and to members of the Council That the general business, general scientific, and representative meetings be held at the same place and time of year, but separately, and on such days and at such hours as not to conflict with one another, and that

Representation of Divisions

[illegible] d the [illegible] d one [illegible] up of [illegible] such [illegible] with [illegible] ected [illegible]

Mode of Election

[illegible] United Kingdom each representative be elected in a general meeting of the constituency held during the three months immediately preceding the annual meeting and in the colonies and India either in the aforesaid manner or by voting papers, as may be determined by the constituency That the [illegible]

Payment of Expenses

[illegible] each such [illegible] meeting [illegible] that he [illegible] meeting [illegible] ncil

Clause No 17 was agreed to as follows down to Subsection II, part A —

Business of Annual Meetings

17 That the business of the annual meetings named in the preceding *recommendation be severally restricted to the following matters*—namely —

General Business Meeting

(A) The general business meeting

Election of Officers

(i) To elect such officers and members of committees as, by the articles or by laws, may be appointed to be so elected

Consideration of Financial Statement of Council and Reports of Committees.

(ii) To consider the annual financial statement presented by the Council the reports of committees instructed to report to such meeting, and motions relating to the adoption of such statement, or of such reports in whole or in part

Dr E J SLADE-KING (Ilfracombe) moved, and Dr J GROVES (Carisbrooke) seconded, the following, which was duly carried —

That it be an instruction to the committee in Recommendation A to be appointed to frame the [illegible] do present to the meeting of [illegible] and expenditure for the con[illegible] mate to be furnished to the [illegible] month before each meeting so that the divisions may know what they have to deal with

The remainder of Clause 17 was then carried as follows :—

The General and Sectional Scientific Meetings.

(B) The general and sectional scientific meetings to deal with such matters relating to the medical and allied sciences and in such manner as may be determined by the Council

Representative Meeting—Election of Officers

(C) The representative meeting

(i) To elect such officers and members of committees as, by the articles or by laws, may be appointed to be so elected

Consideration of Reports

(ii) To consider reports of the Council reports of committees instructed to report to such meeting, and motions relating to the adoption of such reports in whole or in part.

Questions from the Council

(iii) To deal with matters submitted by the Council to the divisions for the purpose of decision by the representative meeting

Alterations of By laws.

(iv) To deal with proposed alterations of the by laws of which three months notice has been given

Medical Politics and Ethics

(v) *To consider any resolutions relating to the honour and interests* of the medical profession which have been adopted by any division and submitted through the *Journal* to the consideration of all the divisions not less than three months previously

The following clauses were then agreed to :—

Voting

18. *That in meetings other than representative meetings each person* entitled to vote have one vote and no more

Representative Meeting

[illegible] ting representatives of divisions o[illegible] [illegible] e latter case voting be as a rule, by [illegible] rity of those present determine that [illegible] n every representative shall record as [illegible] in the division or group of divisions [illegible] ting upon any matter upon which a constituency has passed a resolution within three months

Representative to Vote as Instructed.

immediately preceding such meeting the representative of that constituency be under obligation to vote in accordance with such resolution

Chairman

That the representative meeting at the commencement of its annual session, elect a chairman for such session, who shall be an *ex-officio* member of the Council

Quorum General Business Meeting

That no business be transacted in any general business meeting unless there be present 100 members nor in any representative meeting unless there be present one-half the number of representatives appointed to attend such meeting

Powers of General Business and Representative Meeting

19 That a resolution of the ann[illegible] interests of the [illegible] the adoption thereof

Referendum at Instance of Council

[illegible] observations as the Council [illegible] special meetings of all the [illegible] resolution shall not be valid [illegible] majority of the members of [illegible] said special meetings of the divisions

Annual Subscription Grant to Branches

[illegible] be uniform and inclusive that the [illegible] ing 30s as may [illegible] 4s per annum, [illegible] made from the [illegible]

Subscription Due.

That the annual subscription be due on Jan 1st in each year and be paid to the central office of the Association

Privileges of Membership.

That each year's subscription entitle the member to receive the Journal of the Association for the current year, to the other privileges of membership of the Association, and to the ordinary privileges of membership of his branch and division

Grant to Indian and Colonial Branches

That the same proportion of each member's total annual subscription be allotted to the Indian and colonial branches and divisions for the expenses of local organisation as in the United Kingdom

Standing Committees

21 That subject to the articles of association and by laws, the *Council and the representative* meeting have power to appoint committees with such powers as may be necessary or convenient and to fix the quorum thereof and lay down rules for regulating the proceedings of such committees

Provided that there be standing committees as follows :—

(1) Journal and Finance.

(1) A Journal and Finance Committee to be appointed by the Council which shall *inter alia* examine into the general working of the office and of the *Journal* and certify the quarterly accounts prior to their being presented to the Council.

(2) Premises and Library.

(2) A Premises and Library Committee to be appointed by the Council, to which shall be referred all matters connected with the library and its management as well as the management of the house property of the Association.

(3) Public Health.

(3) A Public Health Committee to be appointed by the Council, to which shall specially be referred all questions relating to the public health service, the poor-law medical service, and the vaccination service.

(4) Colonial.

(4) A *Colonial Committee to be appointed by the* Council, which shall consider all questions specially relating to the colonial and foreign branches.

Such committee to include the representatives of these branches on the council.

(5) Naval and Military.

(5) A Naval and Military Committee to be appointed by the Council, to which shall be referred all matters relating to the Navy Medical Service, the Royal Army Medical Corps, the Indian Medical Service, and the medical organisation of the auxiliary forces.

Such committee to include the members of these services who are on the Council.

(6) Medico-Political.

(6) A Medico-Political Committee, which shall deal with all matters involving the public relations of the profession not specially referred to other committees, and shall consist of 15 members, eight of whom shall be appointed by the Council, and seven by the meeting of representatives.

Such committee to report to the Council and to the meeting of representatives, to act under the Council, and to have the services of a salaried officer.

(7) Ethical.

(7) An Ethical Committee, which shall advise the Council upon proposed by-laws of divisions and branches relating to professional conduct, shall investigate and report to the Council upon the cases of members whose conduct is to be considered by the Council, shall adjudicate in cases of disputes on ethical questions referred to it by members of the Association, and generally shall advise, and where so directed act for the Council on all questions of professional conduct.

Such committee to consist of not more than 12 members, half to be appointed by the Council and half by the meeting of representatives.

(8) Organisation.

(8) An Organisation Committee, which, subject to the directions of *the Council,* shall deal with all questions of the boundaries of branches and divisions, and the by-laws thereof other than those relating to ethical matters, and advise the Council thereon, and shall exercise such powers as may be conferred upon it by the Council in advising and assisting divisions or branches in the strengthening of their organisation.

Such committee to consist of not more than 18 members selected by the Council as representatives of the various districts of the Association and to have power to add to its number for special purposes a limited number of members specially qualified to assist in its work.

Committee Nos. 7 and 8 to have the services of a salaried officer, who may be the same as that of the Medico-Political Committee.

That the chairman of each Standing Committee be a member of Council. In the case of Committee No. 1 all the members to be members of the Council, but that in regard to other committees where not otherwise specified, such members to be non-members of the Council as the Council may from time to

That the first class travelling expenses of all members attending meetings of Association.

It is further recommended that in the event of the above scheme of reorganisation being adopted by the annual meeting the following special committees be appointed:

Drafting of New By-laws and Articles.

A. A committee, not exceeding 11 in number, to arrange for carrying the same into effect, by the preparation of the requisite articles and by-laws, such articles and by-laws to be forwarded to the Council for submission to the necessary statutory meetings.

Organisation Committee.

B. A committee, consisting of the secretaries of all branches, *ex officio*, and of other members *of the Association* appointed by the Council, to confer with Branch Councils, or with such special committees as may be appointed by branches for this purpose as to the formation of divisions and the necessary changes in the boundaries of branches and to advise the Council as to the same.

Special Colonial Committee.

C. A committee to further consider the organisation of the Colonial and Indian branches and their relation to the Association, and to recommend such further *changes in* the regulations of the Association in reference to these matters as such committee may think desirable.

The following motions were put to the meeting, after having been duly proposed and seconded, and were declared by the CHAIRMAN to be carried:—

That it be an instruction to the committee appointed to draft the new articles and by-laws to consider the desirability of publishing the annual report before the election *of the* members of Council, and, if approved, to include the above suggestion in the new articles or by-laws;

Also, to consider the desirability of the President of Council taking the chair at all general business meetings, and, if approved, to include the above suggestion in the new *articles or* by-laws.

Dr. SARAT K. MULLICK moved:—

That having regard to the fact that pe ow-
ledge of medicine are by law allowed the in
India as fully-qualified practitioners, thi it
advisable that there should be a system of registration to protect the public from charlatans.

Dr. GROVES pointed out that registration throughout the Indian Empire presented political difficulties and considerations. Anything that was done in reference to India had to be done after much consultation with the people who have the interests of the natives of India most at heart. The authorities in India were unwilling to interfere with the rights of hereditary practice.

Surgeon-Major J. B. HAMILTON said that the carrying out of the motion would deprive an enormous number of natives of India of medical assistance. In that country the practice of medicine was an hereditary matter.

The motion was thereupon withdrawn and the proceedings terminated.

THE SECTIONS.

OBSTETRICS AND GYNÆCOLOGY.

THURSDAY, AUGUST 1ST.

Dr. WILLIAM DUNCAN (London) opened a discussion on

When and How to Operate for Fibroids.

He began by a reference to the question, Do fibroids endanger a woman's life? One writer had stated that the mortality of fibroids apart from operation was three cases in 2,160,112, adding that it seemed undeniable that deaths from fibroids apart from operation were excessively rare. Against this they had the opinion of another who quoted 18 cases reported by various medical men in which death was directly due to the condition. It was certain that fibroids might seriously affect the health of the patient, even apart from hæmorrhage. Thus a fatty heart was by no means uncommon; pregnancy often involved great risks, the mortality from various causes having been estimated at as much as 36 per cent., and resulting from miscarriage, rupture of the uterus, or other complications of labour; degeneration of vessels might also occur. On the other hand, there was no doubt that many cases gave no trouble and should be left alone; it was as wrong to say that all cases should be operated upon as to say that no operation should ever be done. The indications for operation were: (1) hæmorrhage; (2) pressure symptoms; (3) rapid increase in size; and (4) complication with pregnancy. In cases of hæmorrhage he advocated that in the first place dilatation should be done in order to remove any polypus that might be present; if the tumour turned out to be interstitial he thought that it was bad surgery to incise the capsule and to give ergot in the hope of expulsion, and he equally deprecated removal by morcellement. The advantage claimed for morcellement was that the uterus was left, but this was not always an advantage. Passing on to other measures, he considered that oöphorectomy had very properly fallen into disuse, since the mortality was not less than that of hysterectomy, it was not always effective, and it was more important to leave the ovaries than the uterus. With regard to Apostoli's treatment he had tried it in 10 cases and had found no benefit from it. Abdominal myomectomy was in many cases the ideal operation for fibroids; he did not, however, advocate it for multiple myomata. Hysterectomy was, then, the best treatment. The old extra-peritoneal operation with the serre-nœud he mentioned only to condemn. The choice of operation finally lay between retro-peritoneal hysterectomy and pan-hysterectomy, and of these he preferred the former as he did not see that pan-hysterectomy presented any special advantages. With regard to vaginal hysterectomy he thought that it had drawbacks and risks that were not compensated by advantages. He had now performed retro-peritoneal hysterectomy in 127 cases, with four deaths, there being no deaths in the last 81 cases. When pressure was the principal symptom the uterus could in some cases be pushed up and held up with a pessary; failing this, removal of the tumour was necessary. Rapid increase in size was generally due to degeneration and required the removal of the growth as soon as possible. The treatment of fibroids complicating pregnancy would depend on circumstances; some went through labour without trouble. In other cases interference was demanded by great pain during pregnancy, and the courses that were open to them were (1) the induction of abortion, (2) abdominal hysterectomy or myomectomy, and (3) waiting till form with the view to the performance of Cæsarean section so as to save the child. With regard to the after risks of hysterectomy, shock and heart failure might often be averted by the administration of liquor strychninæ in three minim doses three times a day for a week before and a week after the operation. With regard to operative details he secured the ovarian and uterine vessels before cutting the peritoneal flaps so that there was a minimum of hæmorrhage; he did not sew up the stump itself but secured the peritoneum over it. The abdominal wall was closed in three layers. Convalescence was usually uneventful, especially when the ovaries had been left behind.

Dr **Cuthbert Lockyer** (London) continued the discussion with a short paper on

A Case of Cystic Fibro-myoma in a Single Woman aged 23 years, Myomectomy, Recovery

The patient had a tumour reaching nearly to the umbilicus and admitted the possibility of pregnancy, which the case somewhat resembled. The os was found widely dilated and a cystic swelling presented. The swelling proved to be a degenerating myoma undergoing spontaneous extrusion and was removed by morcellement; the lower and more solid part of the tumour weighed over two pounds; the upper portion was almost entirely cystic, containing over 30 ounces of yellow fluid. The patient made a satisfactory recovery.

Mr **Alban Doran** (London) laid down the dictum that operative success did not constitute justifiability for operation and held that brilliant operating might nevertheless be bad surgery. He agreed with the indications for operation mentioned by Dr Duncan and endorsed his recommendation of strychnine. He had also found spartein very useful especially in the case of middle-aged women with unhealthy kidneys. The Apostoli treatment was in his opinion much too empirical. Menorrhagia if slight was of no consequence; if more severe it could be checked by ergot; if worse still it was best to do hysterectomy. Even the scientific basis of the Apostoli treatment had been called in question by electricians, and it had been pointed out that if molecular disintegration occurred as was claimed the woman would be either burnt up or blown up. With reference to the complication of fibroids with pregnancy, he pointed out that a fibroid at the fundus usually needed no interference and he deprecated myomectomy during pregnancy as being bad surgery. Of the varieties of hysterectomy he preferred the retro-peritoneal. He laid great stress on having the stump and ligatures all covered over by peritoneum, this applied equally to the ovarian stump. He also strongly advocated the ligature of the uterine vessels under the peritoneum without including the serous coat and a lot of tissue in the ligature. When in doubt as to the position of the vessels it was best to amputate the uterus and to secure the arteries as they spouted; it was better to see and to secure them than to poke about in the dark with a pedicle needle in the broad ligament which had the result not infrequently of missing the arteries whilst the needles however blunt usually damaged the veins.

Mr **Christopher Martin** (Birmingham) said that in considering operative indications the right course was a middle one. Among the indications requiring operation one that had not been mentioned by Dr Duncan was sloughing. Further he believed that sarcomatous degeneration of fibroids was a more common condition than some gynæcologists believed, he had personally seen seven cases in 12 years. As to particular operations a submucous myoma should be removed leaving the uterus; if large myomectomy could usually be done in a woman who had borne children but in nulliparæ it was both difficult and dangerous. There was a wide field for conservative abdominal myomectomy except for multiple fibroids. In the main hysterectomy was no doubt the proper treatment. There was much to be said in favour of both pan-hysterectomy and supra-vaginal amputation. He did not consider the former any more difficult than the latter and it was indicated when the cervix was involved or was the seat of malignant disease. The advantages of supra-vaginal amputation were that there was no resulting communication with the vagina, though this was not necessarily a risk if proper cleansing of the vagina were carried out, it did not involve so much shortening of the vagina as occurred after pan-hysterectomy, there was less risk of wounding the bladder and ureters, less chance of adhesions of bowel to gauze packed in the vagina, and it was often a great point for the patient to feel that a part of her uterus was left though it might be incapable of physiological functions. Vaginal hysterectomy was useful in some cases but it was not indicated in cases of large tumours or where adhesions were present. His own results up to date were 47 abdominal hysterectomies (of which 40 were pan-hysterectomy), with one death, eight cases of abdominal hysterectomy for sarcoma with two deaths, and 33 vaginal hysterectomies, with two deaths.

Mr **Hawkins Ambler** (Liverpool) said that heart disease was often an indication for operation as Dr Thomas Wilson of Birmingham had shown in a valuable paper read before the Obstetrical Society of London. He did not approve of myomectomy for multiple fibroids, for though it might give good results in the experienced hands of Dr William Alexander in most cases the results were bad. He asked the experience of members as to the value of atropine for shock; personally he was disappointed in it. He had had good results from strychnine and also from the use of salines.

Dr **Alfred Smith** (Dublin) agreed in the main with the indications laid down by Dr Duncan but thought that the mere size and bulk of the tumour justified operation in some cases—for instance with servants and governesses who might otherwise be unable to obtain situations. His results up to the present were 101 cases of hysterectomy without a death. He laid great stress on the preparatory treatment of exsanguined and feeble patients. With them he not infrequently did a preliminary curetting to check bleeding and then kept the patient for some months on a course of iron and arsenic with a generous diet. In the prevention of shock it was most important to save mauling the intestines; for this purpose after the tumour had been lifted out of the abdomen he generally brought the abdominal walls together above it with a temporary suture.

Dr **John Campbell** (Belfast) considered that dilatation with curetting required to be used with great discrimination, the operation was all right for small fibroids but in the case of large tumours with a tortuous uterine canal it was dangerous. With reference to the size of the flaps he had observed that in some of his cases there was an unsatisfactory condition of the pulse after operation and he was led to the conclusion that his flaps were too large and allowed of collection of fluid from which a kind of chronic poisoning resulted. He now made the flaps as small as possible.

Mrs **Garrett Anderson** (London) recalled the pre-operative period when fibroids were not interfered with. She had seen some of the risks resulting from leaving them alone. Three cases died from cerebral hæmorrhage; the patients were little over 50 years of age and presented nothing to account for the fatal ending except the previous losses of blood from fibroids. She had also seen cases of malignant degeneration of these tumours.

Mrs **Scharlieb** (London) said that she did not at all believe in Apostoli's treatment; it usually led to peritonitis and the formation of adhesions. The indications for operation were theoretically clear but there was often some difficulty in applying them to individual cases. Even when there was no hæmorrhage or pressure and in the case of women over 50 years of age degenerations might occur. One such patient whom she saw consulted one of the leaders of the profession who never operated himself or [illegible] operation. He said that such a thing as operation was not to be considered and the next thing she heard was that the patient had died without operation from the sloughing of a myoma. She related several other cases of degenerations of myomata and remarked that the difficulty was to know which cases would undergo such degeneration and which would not. That these changes were common would admit of no doubt. In conclusion she related a case of myomectomy with conservation of the uterus and appendages in a girl aged 15 years.

Mrs **Stanley Boyd** (London) endorsed Dr Alfred Smith's statement that the mere size of a tumour was often sufficient reason for operating. Such a tumour was a deformity and apart from the difficulties in obtaining situations referred to by Dr Smith it might expose a woman to adverse criticism which might have a very serious effect. In other departments of surgery the removal of deformities was allowed and why not in the case of myomata? The speaker had had good results from morcellement and also from vaginal hysterectomy in cases where the tumour was no larger than a four month gestation. She advocated conservative myomectomy, and pointed out that more information was wanted as to the course and results of labour after this operation.

Trendelenburg's position diminished shock by allowing the intestines to fall back out of the way of manipulation.

After some observations by Mr. BOWREMAN JESSETT (London)

Dr. AUST LAWRENCE (Bristol) remarked that before coming to the position of the obstetrician mentioned by Mrs. Scharlieb who never advised operation he would take down his door-plate. There was no doubt, however, that many women went about with fibroids without inconvenience. He agreed with the indications for operation laid down by Dr. Duncan. He had tried Apostoli's treatment in five cases and came to the conclusion that such benefit as accrued was received by the physician and not by the patient. With regard to the complications of pregnancy, he had had eight patients with fibroids whom he had attended in their confinement, and among them they were delivered of 17 children. An important thing was not to allow the uterine muscle to get over-tired; and half the cases were delivered with forceps. In some cases the tumour markedly diminished in size after labour. He held, therefore, that a fibroid tumour was not necessarily a barrier to marriage, and as long as the tumour presented no obstruction to delivery pregnancy might usually be allowed to go to term.

After some remarks by Dr. WARD COUSINS (Southsea) and the PRESIDENT (Professor J. W. BYERS), Dr. WILLIAM DUNCAN replied.

Dr. F. JAYLE (Paris) read a short communication on a New Gynæcological Position, which was a modification of Trendelenburg's position used for vaginal examinations and operations.

The three following papers were also read:

Dr. ALFRED SMITH (Dublin): A Successful Laparotomy for Abdominal Pregnancy with Removal of a Full-term Fœtus. Placenta and gestation sac *en masse.* The specimen was shown.

Mrs. STANLEY BOYD (London): A case of Twin Pregnancy, Extra-uterine and Intra-uterine.

Mr. HASTINGS GILFORD (Reading): Ovarian Pregnancy.

STATE MEDICINE.

THURSDAY, AUGUST 1ST.

A discussion was opened by Dr. A. C. HOUSTON (London) on

Enteric Fever in its Public Health Aspects.

He said that he was struck by three things: 1. That notwithstanding the progress of science and the greater efficiency of the public health service they found themselves at the beginning of a new century unable to stamp out a disease that was, nevertheless, still classed as a preventable one. All that could be said at the present time was that the mortality from it was less than it was some years ago. 2. That the knowledge, skill, and resourcefulness of the members of the Army Medical Service and their high devotion to duty had failed to prevent their troops in South Africa from suffering from enteric fever to a most deplorable extent. 3. That during the last few years some notable discoveries had been made in connexion with the bacteriology of enteric fever and fresh light had been thrown on the modes of dissemination of the disease. One of the most remarkable bacteriological discoveries of recent times was the "agglutination phenomenon" or "clumping reaction," terms applied to the now well-known fact that the blood of an enteric fever patient when mixed with an emulsion of living typhoid bacilli caused a specific reaction to take place; this showed itself in an embarrassment of motility followed by a clumping together of the bacilli. Dr. D. S. Davies used this test in tracing the epidemic of enteric fever at Bristol. Speaking generally no microbe other than the bacillus typhosus yielded the positive result described. There were exceptions, however. The serum of typhoid fever patients might react strongly to Gärtner's bacillus. The implicated Belfast water-supply that "clumped strongly with the blood of enteric fever patients was found to contain "coli-like" microbes. The means for differentiating the bacillus typhosus from the bacillus coli had been extended; it was known that they were linked by intermediate forms. It was recognised that the typhoid bacillus was the cause of enteric fever, but as regards those other microbes there was no such knowledge. In the method of isolating the bacillus typhosus from sewage and water-supply much progress had not been made, but success had been arrived at in this respect abroad. It might be that the bacillus typhosus, existing saprophytically, differed morphologically and biologically from the bacillus typhosus after it had gained a foothold in the human organism. Dr. Houston then proceeded to deal with water, milk, and shellfish in relation to the dissemination of enteric fever. Water and milk had long been recognised as agents in disseminating enteric fever, but shellfish had lately been the subject of investigation. The bacillus typhosus might persist in sea-water for two or three weeks and in the interior of living oysters placed in sea-water artificially polluted with the bacillus typhosus for 18 days. The typhoid bacillus had been isolated from the body and liquor of an oyster derived from a suspicious source. The danger was not a constant one because although oysters were apt at one time or another to be brought into sustained relation with objectionable matters, the contamination was happily but seldom of specific sort. In regard to soil in its relation to typhoid fever the bacillus typhosus remained alive for long periods in sterilised cultivated soils, but sterilised virgin soils were inimical to its growth. It was held that in the deep layers of soil the conditions might be more favourable to the continued existence of the enteric fever bacillus. Flood water came under grave suspicion in the spread of enteric fever, because during storms it was not uncommon for the filtration of water to be inefficient. At the present time sanitarians took the view that the gases from sewers and cesspools, sewage, and polluted rivers were not usually bacterially objectionable but tended to depress the vitality of weakly persons and rendered them prone to "catch disease." It might be suspected that many of the cases of enteric fever traced to inhalation of impure ground air might have been due to drinking specifically contaminated articles, such as water and milk, &c. Laboratory experiments formed an unreliable index of what occurred in nature. The endemic prevalence of enteric fever in some localities with outbreaks without any apparent cause was difficult to explain unless it was assumed that the bacillus typhosus existed saprophytically in soil or in ground water. It had been shown that the bacillus could remain alive in various situations in the human body for months and years. The stools were only one of a series of agents by means of which the disease was spread, and the patient, after his seeming restoration to health, might carry about in himself the seeds of infection for months and years. It was suspected that the danger of flies and insects and vermin conveying contagion was a real one. Until positive evidence was forthcoming to the contrary it would be wise to regard the effluents from bacterial beds as no more safe in their possible relation to disease than crude sewage. The attention that had been directed to typhoid bacilluria had thrown light on the spread and persistence of the disease. Dr. Houston then discussed fully the danger of infection from fried fish and gave details of an outbreak of enteric fever where the fried fish purchased from a particular shop seemed to have had a nearly universal attraction for the persons attacked by the disease. The distribution of affected houses showed a grouping about this shop as a centre, and in some families it was the fried-fish eaters who were attacked. In an outbreak ascribed by some to fried fish the disease was said by one observer to have been spread by infected mangles. Certainly that medium of infection had hitherto escaped recognition. Dr. Houston concluded with some remarks on prophylaxis. He considered that the preventive inoculation with Wright's vaccine was most serviceable for persons going abroad. It had been clearly demonstrated that urotropine was an almost specific remedy in cases of typhoid bacilluria, and Dr. Houston digressed at this point to state emphatically that the potentialities for evil of a typhoid fever convalescent suffering from typhoid bacilluria were so great as to be almost inconceivable. No one doubted that efficient sand filtration was a great safeguard, but there was no reliable evidence to show that it did more than greatly lessen the danger. The general measures which had governed sanitarians in the past remained the same to-day—viz., protection of water-supplies from excremental pollution, securing all articles of food from objectionable communication, keeping the drains and sewers in good order, and disinfecting the stools and urine of patients suffering from enteric fever. The recognition of the dangerous affection known as typhoid bacilluria must have a most important influence in controlling the spread of the disease.

Dr. F. A. DIXEY (Oxford) read a paper on the

Vital Statistics of Enteric Fever.

His conclusions were that the death-rate from enteric fever in London was a fluctuating one, but had on the whole materially diminished, the most marked descent having occurred about 16 years ago. The seasonal relations of enteric fever remained fairly constant from year to year, but there seemed to be a tendency, at least in years of low general prevalence, towards a progressive flattening of the autumnal maximum. A comparison between London and New York in respect of climate and enteric fever death-rate indicated that some meteorological conditions, especially perhaps temperature, were factors in the activity of the enteric infection. The relation however, was not of such a kind as to make itself apparent from year to year in one given locality. It was probable that the diminution in the death rate of enteric fever was really somewhat greater than it appeared to be from the inclusion in former times of enteric fever cases under other heads, notably typhus fever and simple continued fever. This source of error, however, was never very important and it was practically non existent. The case mortality of enteric fever was almost stationary and seemed likely for the present to remain so.

Dr W. G. SAVAGE (Cardiff) said that there was too great a tendency to accept the opinion of the bacteriologist as final.

Dr H. HANDFORD (Nottingham) addressed the meeting on the importance of direct infection in this disease and protested against the routine use of large doses of urotropine.

A communication from Dr E. M. SMITH (York) was read in which he referred to the ease with which infection could be carried by flies from the open middens used in York.

Dr A. R. REYNOLDS (Chicago) said that Chicago was supplied with water from Lake Michigan by four tunnels and it had been observed that the mortality from typhoid fever and from acute intestinal diseases followed each pollution of the supply, the first in about five weeks and the second in about one week. In January, 1900, the sanitary waterway was opened that carried the city sewage into the Mississippi valley, thereby reducing the mortality from typhoid fever. The Chicago departmental laboratory supplied physicians with its services entirely free in making diagnoses by the Widal test.

Dr A. K. CHALMERS (Glasgow) discussed the seasonal curves of enteric fever in Glasgow. These were two points of increasing prevalence, one in the autumn and the other in the spring. In a winter of severe frost some years ago no spring increase followed.

Dr J. GROVES (Carisbrooke) considered that there was expected from the bacteriologist that which was altogether beyond his power. He gave the history of an outbreak of enteric fever due to a supply of chalk water. The local authorities were lulled to a feeling of security by the bacteriologists and chemists declaring the water to be excellent, containing no organic impurity and with less than 150 innocent micro-organisms to the cubic centimetre. The problem was cleared up by means of "spot maps" at great expense to all concerned.

Dr F. T. BOND (Gloucester) stated that he had *not* observed any special liability to enteric fever in the colliery districts under his care. He had not come across a single case of infected milk causing enteric fever during 28 years.

Mr J. A. WANKLYN said that water free from organisms but charged with organic matter was a highly dangerous water because it was a culture medium.

Mr HERBERT JONES (Hereford) said that after the introduction of "water carriage" typhoid fever decreased in the Rhondda valleys.

Mr W. C. C. PAKES (London) detailed a useful test for differentiating the bacillus coli from the bacillus typhosus by means of a sodium formate medium.

Dr J. M. MARTIN (Stroud) propounded the question whether local authorities ought to sterilise their chemically pure effluent or whether the bodies who drew on river water should purify it.

Mr G. H. FOSBROKE (Worcester) cited cases of enteric fever in which the infection was carried 12 miles by water. He had concluded in certain outbreaks that the disease arose from polluted soil.

Dr HOUSTON, in reply, said that sanitary authorities did not sufficiently recognise the difficulties of the bacteriologist. Sputum was not usually credited with special infective capabilities but should be viewed with suspicion. He did not agree that urotropine should not be administered; to withhold it in some cases was to encourage the spread of enteric fever. The exceptions to the utility of Widal's test were not sufficient to detract from the value of the test. In the failure to diagnose contamination of water described by Dr Groves it was difficult to understand the mistake. In regard to Mr Wanklyn's views he urged that the bacteriologist could detect minute excremental pollution outside the reach of chemical analysis. He recognised the value of Mr Pakes's test with sodium formate medium and would try it in the future.

PSYCHOLOGICAL MEDICINE.

THURSDAY, AUGUST 1ST.

Dr ROBERT JONES (Claybury Asylum) opened a discussion on

Puerperal Insanity.

After referring briefly to the importance of reproduction and to the nervous basis of the reproductive emotions he stated that gestation was attended with much nervous disturbance in many women and with some nervous disturbance in all women. Insanity actually occurred but once in every 700 confinements. The reports of the Commissioners in Lunacy for the years 1894-98 inclusive showed that 8·4 of women admitted to asylums in the pauper class and 7·2 in the "private" class were subjects of insanity due to the puerperal state or to pregnancy or lactation. The statistics of Claybury Asylum for 1900 corresponded very closely with these figures, and Dr J. Warnock of the Cairo Asylum gave similar figures for Egyptian women. Taking the total of 3500 female patients admitted to Claybury Asylum during the past eight years, exclusive of transfers from other asylums, it appeared that 259 were cases of insanity of pregnancy, the puerperium, or lactation, distributed as follows: 56 were cases of insanity of pregnancy, 120 were cases of puerperal insanity in the stricter sense—i.e., occurring within six weeks of confinement, and 83 were of later development and associated with lactation. It was suggested that no particular type of insanity was associated with pregnancy or lactation, but the insanity of the puerperium was different in that it presented a marked delirium with wildness and delusions of a hallucinatory character in which religious and erotic manifestations were prominent, so that an almost distinct nosological entity might be recognised, a view, however, which he confessed was not supported by high authorities. As to illegitimacy it appeared that 12 per cent. of the 259 cases from the records of Claybury Asylum were single women and that the outbreak of insanity was twice as frequent during pregnancy in these cases as in the puerperium. The incidence of illegitimacy in the general population varied greatly, being low in Middlesex and Essex, high in Cumberland, and probably higher still in Scotland. Of the married women who had had a first attack no less than one third had subsequent attacks in their second (or later) confinements. One patient had had 12 attacks of insanity with as many confinements and another had nine. Both cases terminated in chronic and incurable dementia at the menopause. Of the puerperal cases more suffered from mania than from melancholia. Of 120 puerperal cases one only was epileptic. Of the 83 lactational cases a greater proportion suffered from melancholia or depression than from exaltation. The onset in the puerperal cases was generally sudden and maniacal; in fact, the sooner the outbreak of insanity followed confinement the more acute were the symptoms. The almost unanimous early symptom of puerperal insanity was insomnia followed by a feverish and anxious restlessness. Suspiciousness, loss of appetite and a proneness to delirious excitement followed. The symptoms of puerperal mania occurred within the first two weeks of confinement in 40 per cent. of cases and 18 per cent. more occurred during the third week. It was important to pay early attention to sleeplessness and headache in puerperal women. Suicidal promptings were present in 21 per cent. of the puerperal cases, increasing to 47 per cent. among lactational cases. In one case the conversation of the nurse that infants were occasionally removed piecemeal acted as the apparent exciting cause of puerperal insanity in a nervous and susceptible woman. One predisposed woman hearing of the confinement of the Princess May developed the delusion that she was the princess. It was probable that both bodily conditions such as septicæmia, exhaustion and the like, co-operated with mental strain and anxiety in producing puerperal insanity. The puerperal woman should be protected from both classes of exciting causes. In puerperal insanity the woman usually suffered from delusions concerning the identity of those near her and even failed to recognise her own identity or that of her infant. She developed marked antagonism to her husband and displayed both eroticism and indecency—a habit which shocked and alarmed her friends and relatives. A glaring wild look characterised this stage, the skin was pale and sallow, and repeated yawning indicated clearly a marked degree of exhaustion. Of 120 puerperal cases 88 were first attacks. One insane woman discharged from Claybury Asylum was admitted afterwards to another institution with puerperal insanity. She subsequently bore seven children, five of whom became insane. In was questionable whether hysteria in early life increased the possibility of a mental breakdown in the puerperium, for it must be remembered that to many girls marriage fulfilled a natural expectation and it thus might lessen the liability of mental breakdown at the climacteric which the single state predisposed to. With reference to heredity it was found that 122 out of the 259 cases referred to in this paper had some hereditary predisposition to mental or physical breakdown, including both direct and collateral taints of insanity, epilepsy, suicide, alcoholism, and phthisis. Home treatment should be adopted in cases where means permitted, the infant's and husband's presence being avoided, as these frequently tended to produce infanticidal impulse or eroticism. The prognosis as to recovery was good for first attacks, but after second or subsequent attacks, or when puerperal insanity appeared after confinements late in life, the prognosis was bad and the insanity was apt to persist and to become chronic. Many cases of acute puerperal mania tended to pass into acute dementia, and, contrary to Clouston's and Savage's, experience at Claybury Asylum had shown that numerous and frequent relapses were more common in these cases than was generally believed. Special watchfulness was necessary in cases of lactational insanity to guard against the patient's lapsing into a low state of nutrition with tendencies to gangrene or pulmonary phthisis. Albuminuria was not common in puerperal insanity and when it occurred the prognosis was grave. Of the recoveries from puerperal insanity nearly half occurred before the expiration of four months from the outbreak. The death-rate was highest in the insanity of pregnancy and lowest in puerperal insanity. With regard to pathology it was suggested that a slight toxæmia of the mother's blood was produced by waste products excreted from the fœtus; some observers called this a state of anæmia owing to a diminution of the red corpuscles in the maternal blood, while others had drawn attention to peptonuria and an increase in the toxicity of the pregnant woman's urine After confinement the morbid and effete material which was taken into the maternal circulation during early uterine involution tended to produce, in those predisposed, an irritation of the nervous system, especially if the secretory and excretory functions were in any way impaired or inefficient. At this period saprophytic bacilli gained entrance to the blood and septicæmia and pyæmia rapidly developed. The tongue then got foul, dry and coated, sordes formed on the lips and teeth, the skin was dry and hot, and the urine was scanty and concentrated. Obstinate constipation might be present In cases where there was no fever but where an acute delirium occurred lasting for several days it was possible that some unknown poison in the blood acted on the brain in a manner like unto alcohol. As regards treatment the dictum of Gooch, that no medicinal agents could relieve a disordered mind except indirectly through the disorder of the body with which it was associated, had to be borne in mind. These causes had to be ascertained and treatment directed to them. Cases of the insanity of pregnancy required constant vigilance to prevent suicide. The patient was suitable for asylum treatment or where means permitted she might be treated at home The general treatment was a light dietary, bright surroundings, regulation of the bowels by saline aperients, and sleep, the latter being secured by the aid of chloral and bromides in combination. Complications which might arise, such as eclampsia, must be dealt with after the methods of obstetric science. Insanity occurring after the puerperium needed more special treatment. and it would be well to make it a rule in all cases occurring within six weeks of parturition to treat the patient at home The special dangers of infanticide and suicide should be guarded against and the avoidance of the stigma of asylum treatment would be an intense relief to the mother who during her convalescence would think she had only suffered from "fever" and not from insanity. The essence of general treatment might be summed up in generous diet, liquid and easily assimilable, administered by the stomach tube if necessary. Food should be given during every quiet interval, as exhaustion was a marked feature Eggs, beef-tea, milk, malt liquors and malt extract, and cod-liver oil might be given to the patient, while the bowels should be kept regularly and freely open with calomel, jalap, podophyllin, or croton oil. Sleep must be secured, and for this purpose sulphonal, paraldehyde, and the combination of chloral and bromides were the best therapeutic agents in his experience. Opium and morphia were unsuitable owing to the stimulating effect on the brain and the arrest of secretions produced by these drugs. The anæmia should be combated by the use of iron, strychnine, and digitalis. A return of the menses might be regarded as the forerunner of mental improvement. A condition of semi-stupor might mark the stage of convalescence, and at this stage the patient's mind should be roused and diverted by change of scene and bright surroundings. In all puerperal cases vaginal douches might be given with solutions of boric acid, permanganate of potash. or carbolic acid. Where a portion of membrane or clot was retained in utero dilatation of the cervix and curetting of the endometrium were recommended. What had been said about tonics, diet, and fresh air applied with greater force to the treatment of lactational insanity. Stimulants should be administered with great caution, as the alcoholic habit might be contracted and continued after recovery had set in.

In the discussion following the above paper,

The President (Dr. J. B. Spence of Lichfield), after thanking Dr. Jones, stated that though agreeing in the main with the paper he must disagree with the remark that puerperal cases that break down early after confinement should be treated, if possible, at home for a period of at least six weeks. From a long experience of such cases he was convinced that the earlier the cases of puerperal insanity came into an asylum the better were the prospects of recovery for the patient.

Mr. Josiah Oldfield (London) spoke at some length on the medico-legal aspects of infanticide by a woman recently confined, and argued that evidence pointed to the fact that the stresses of pregnancy were responsible for a considerable percentage of mental disturbances in women. In such cases the woman recently delivered of a child was wholly or in part irresponsible for her actions. It was their duty to teach jurors and the public the doctrine that in such cases of infanticide where a woman broke through the strongest ties and instincts that bound her to her offspring (the protective instinct of motherhood). and attempted to destroy the life of her infant, this in itself should be looked upon as *prima facie* evidence of her irresponsibility, and that therefore the onus of proof of sanity and responsibility should fall upon the prosecution and not its disproof upon the defence.

Dr. James G. Soutar (Gloucester) said that in the district where his practice lay. and amongst the well-to-do. puerperal insanity was not a common disorder. Out of the 500 female admissions during recent years at Barnwood House, Gloucester, only 10 were cases of puerperal insanity. and the striking fact in regard to them was that those who had been admitted within four weeks of the onset of the attack made the best recovery.

Dr. W. Lloyd Andriezen (London) referred to the moral factor predisposing to insanity in cases of illegitimate births, puerperal insanity being twice as common (or, according to Dr. Jones, four times as common) after illegitimate as compared with legitimate births. He referred to the problem of racial predisposition and instanced the Jewish race in the United States, Russia, and Austria, where, according to recent observers, puerperal insanity was twice as prevalent amongst Jewesses as compared with the native population A special neuropathic predisposition also existed in some women, for of two pregnant women going through the stresses of parturition and the puerperium under similar conditions the one might develop an acute delirium with hallucinatory excitement lasting for weeks—in other words, acute mental confusion—whereas the other passed through a little restlessness and irritability with a mild pyrexia, lasting two or three days and leaving no bad after-effects. Such a fact, of every-day experience, showed that a fundamental difference existed. From an etiological point of view he recognised two distinct groups of the puerperal psychoses. In the first group the causes were septicæmia with or without auto-intoxication acting on a basis of cerebral exhaustion; in the second group a psychopathic predisposition existed and but slight stresses were required to excite mental confusion and delirium. In the classification of the puerperal insanities the first place should be given to acute mental confusion; this was the fundamental clinical condition and it was allied to the "hallucinatory delirium" of Mendel and was recognised by Kraepelin and the French school as a nosological entity. A description was given of the microscopic pathological changes found in the brain in a fatal case—viz., extensive destruction and "dusty" chromatolysis of all the layers of nerve-cells in the cerebral cortex, especially the large pyramidal cells, and a peculiar brownish pigmentary degeneration throughout many of the cells and the small amount of perivascular changes in the brain. It was claimed that puerperal insanity had decreased during the past three decades in large towns and reference was made to the sanitary records of Boston and Philadelphia, where the ratio of puerperal insanity to total labour cases had fallen steadily since 1880, the date when antiseptic measures were adopted widely and generally in obstetric practice. It was therefore evident that the development of aseptic treatment in parturition and the puerperium was an important practice in the prevention of some forms of puerperal insanity. The limitation in the production of neuropathic girls by forbidding the marriages of those afflicted with taints of insanity, epilepsy, and the like was another means of prevention, but the advice of the mental physician, though solicited, was seldom followed and it would take many years to educate public opinion, though it was their duty as alienists to do all they could in this direction.

Dr S. J. COLE (Colney Hatch) corroborated Dr Jones as regards the somewhat increased prevalence of puerperal insanity among the private classes, the strains of parturition being felt more among cultured women than in the poorer classes. He emphasised the neuropathic taint as playing a rôle of perhaps greater importance than septicæmia and *toxæmia but was of opinion that the causation was compound* as in the other insanities.

Dr FLETCHER BEACH (London) stated that the marriage of neurotic persons was on the whole to be discouraged, especially when epilepsy or insanity was present. With regard to the milder neuroses, however, he would not absolutely prohibit marriage because children with exceptional abilities and brilliance were sometimes the offspring of slightly neurotic fathers or mothers. He also dwelt upon the importance of diet in puerperal cases as in epileptics.

Dr HARRY CAMPBELL (London) pointed out that in order to maintain a high level of racial health it was necessary that those who fell below the standard of health should abstain from marrying and propagating their kind. The view of sanitarians that it was merely needful to this end to secure hygienic conditions was a dream. He thought it was an accepted belief that any woman who had been insane after childbirth should be prevented from conceiving again and pointed out that the so-called "mental" causes of insanity operated essentially by deranging the functions of the body, and that certain emotions such as fright gave rise to profound bodily changes even in animals. The toxic factor was an important one in determining insanity, both in pregnancy and in the puerperium, because the nutrition of the body was at these times in a state different to that at other times.

Dr J. HADDON (Hawick) said that no microbe could grow without a suitable soil, just as clover could not grow in certain fields unless the right manure was put in. So it was in the human body, and he believed that over-eating was one of the conditions which formed the nidus for such microbe. A restricted diet cured some cases of epilepsy—a disease closely allied to insanity—and it might be that a greatly restricted diet would be helpful in diminishing the predisposition to insanity, including puerperal insanity of microbic origin.

Dr SAMUEL GRIFFITH (Portmadoc) said that in his long experience as a general practitioner he had noted that the patients suffering from puerperal insanity were either sthenic with strong hereditary taint or rendered asthenic with difficult and instrumental labours. He looked upon puerperal insanity as being septicæmic or hereditary. He believed in the home treatment of such cases, the asylum being made use of when the former failed. Many cases would get well with good feeding, strict cleanliness, and rest for both body and mind.

Dr EDWIN LASMORE (Banstead Asylum) said that there was a disease which could be properly termed puerperal mania characterised by an attack of excitement during the puerperal state, febrile temperature, hallucinations of sight, and delusions of identity. The group of symptoms seemed to him to be of such a nature as to point to a toxæmia with characteristic clinical features and he believed it was hereditary. He had faith in the efficacy of opium in puerperal mania and to secure proper effect the drug should be given in large doses up to 20 or 30 minims.

Dr ROBERT JONES, in replying at some length, appreciated the value of the medico-legal criticisms of Mr *Oldfield and believed that legal experience had borne out* the view that there might be changes in women during pregnancy, parturition, and the puerperal state amounting to mental alienation, a point which could not be disregarded in cases of infanticide following labour. He was impressed with the great necessity of kindness, patience, and tolerance in treating puerperal cases. His experience as regards puerperal cases with marked melancholia was that recovery was delayed in such cases. His experience of private cases agreed with that of Dr Soutar as regards the rate of recoverability. The remarks of Dr Andriezen on the moral factor and on illegitimacy deserved serious attention and he entirely agreed with those remarks. The same applied to the observations cited of the diminished incidence of puerperal insanity since the introduction of antiseptic methods. As to the distribution of puerperal insanity among the Jews his impression was that in England they probably kept their women at home when suffering from puerperal insanity either until recovery or until the case became chronic. He quite agreed that acute mental confusion of a hallucinatory and delirious character was the common feature in puerperal insanity, but this had not been recognised by authorities in this country as a nosological entity. He could supplement the pathological findings of Dr Andriezen by referring to a similar case described by Dr van Gieson of New York, who found similar *changes in the* Nissl's granules and pigmentary changes in the nerve cells in acute delirium. Dr Harry Campbell's interesting observations were welcome from the philosophical standpoint—viz., the prevention of insanity by forbidding the marriage of neurotic persons. This was a counsel of perfection thankfully received and promptly disregarded by candidates for matrimony. In certain States of North America such marriages were recently forbidden by law. He agreed with Dr Campbell as to the results of the emotion of fear in producing *bodily disturbances. To the remarks of* Dr Fletcher Beach as regards the marriage of neurotic persons the same remarks he had just made applied. He agreed with Dr Cole that mental shock was more felt in the educated classes and would thus go further to produce puerperal mania which might in such cases be very distinctly of neurotic origin. In reply to Dr Lasmore he stated that both temperature and pulse had a marked bearing upon prognosis, but that a febrile temperature was comparatively infrequent in some marked cases of *acute puerperal mania*. As to heredity, the result of inquiries showed that maternal heredity was met with twice as frequently as paternal heredity in the puerperal and lactational cases. The President's remarks as to early treatment in asylums deserved great respect, especially for pauper cases, but in the case of the well-to-do the stigma of having been in an asylum was keenly felt and if possible this should be avoided by home treatment.

Dr F. W. EDRIDGE-GREEN (*Hendon*) *contributed a paper* dealing with the

Evolution of a Perceptive Centre.

By a perceptive centre was meant the portion of brain having the function of conveying to the mind information concerning a sensation. They knew that nerve impulses differed in accordance with the character of the physical stimuli giving rise to them, and the theory he would put forward was that those physical stimuli which differed most were first recognised by man as different. In illustration of this the evolution of the colour sense was discussed. All the facts which could be gained from the study of the words used for colours in ancient literature (e.g., Greek) and the examination of healthy and colour-blind natives from savage and primitive races of man showed that the sense of light was developed first and the sense of colour afterwards. Those colours which differed most in their physical aspects—which differed most materially in their physical aspects—i.e., wave-lengths—were the first to be perceived as different—viz., red and violet. As the cerebral visual centre developed in man the capacity for recognising other colours would be superadded, so that early man passed through the various stages of colour-blindness, the capacity for colour perception in its present form being very slowly developed. The rainbow in the [illegible] appeared to primitive man first as a bright grey in the middle with a tinge of violet at one border and a tinge of red at the other. This would correspond to that degree of colour-blindness met with occasionally and which preceded total colour-blindess. The recognition of green was a later development in the colour-sense, and as evolution proceeded a fourth colour, yellow, was recognised at the junction of the red and green. He had never met any person who was able to see more than seven different colours in the spectrum. The same theory of evolution applied to the other perceptive centres, such as the perception of pitch by the ear.

In the discussion following the above communication

Dr. LLOYD ANDRIEZEN stated that various observers could distinguish according to their capacity from four to seven colours in the spectrum. He was himself able to discriminate red, orange, yellow, green, and greenish-blue, blue in the strict sense, violet, and the lavender-grey ultra-violet. The infant at first differentiated luminosity from darkness, and from a limited number of observations he believed that blue was first appreciated by the child and red soon afterwards. The perception of green was a later development. From experiments he thought that probably the yellow-green region—the region of maximum luminosity in the spectrum—was the last to be discriminated by man in the evolution of his colour-sense because the purely luminous effect was here at its maximum and therefore would obscure fine differentiation. The evolution of every sensory centre (visual, auditory, or cutaneous) took place in coöperation with its special kinæsthetic auxiliary centre and he thought that exercise of the latter would help in the development of the former. He inquired if cases were observed of the order of dissolution of the colour sense.

Dr. ROBERT JONES said that in some languages such as Welsh the same word was used to designate both blue and green. The grass was blue (Welsh "glas") in Welsh, an indication that blue was the colour first recognised by the primitive Welsh, who at a later stage in the development of their colour-sense extended the application of the term to the nearest colour allied to blue—viz., green. He had dressed his two children in coloured dresses and concluded that they preferred blue overalls. The occurrence of Daltonism was an instance of defective development of the colour-sense, a reversal to an ancestral type of evolution. He agreed with Dr. Andriezen as to the great part played by "motor" sense in the evolution of the special senses, and he believed that its growth could be best studied in children, which must prove an interesting as well as necessary study.

Dr. EDRIDGE-GREEN, in reply to questions, said that he found the order of development of the colour-sense in children to be as follows: first red and violet, then green, then yellow, and lastly blue. In Greek and many other languages besides Welsh there was but one word for both "blue" and "green." The confusion of green and blue was a very common form of colour-blindness. He had noted in a case of general paralysis that the order of dissolution of the colour-sense was the reverse of the order of evolution; and with reference to heredity he mentioned a family of nine persons—one an artist and eight musicians—all of whom were colour-blind.

Dr. JOHN TURNER (Essex County Asylum) contributed a paper on

The Physical Basis of Melancholia.

In melancholia changes were met with in the pyramidal and giant nerve-cells of the brain which were apparently identical with those produced in the motor bulbo-spinal nuclei (hypoglossal and lumbar) of animals by severance of the motor nerves. When such changes were marked dementia was present. Alcohol and traumatism were also capable of setting up similar changes in the nerve-cells. Many years ago Dr. Wiglesworth of Rainhill Asylum described changes in the cerebral nerve-cells in melancholia, and recently Dr. Adolf Meyer had published several cases with descriptions of the pathological changes in the cells. In cases of rapid dementia of alcoholic origin the changes were present in a more marked degree. Dr. Turner then gave the clinical histories of cases of melancholia in which at the necropsies the brain cells showed pathological changes which he tabulated as follows:—1. Cerebral cortical cells. These showed swellings of the cell bodies, displacement of the nucleus to the periphery of the cell, and chromatolytic changes (disintegration) in the central part of the cell body so that this part appeared pale, blurred, and "washed out" in appearance, while the peripheral part was still full of darkly-staining chromatic bodies. These observations referred to the giant and large pyramidal cells. The changes affected all parts of the cortex examined, but were more clearly marked and affected a larger proportion of cells in the ascending frontal convolutions. The very large pyramidal cells met with in the occipital lobe were almost always similarly implicated. The cells of the hypoglossal nuclei were normal, but the cells in the vagus, lateral, ambiguous, and cuneate and gracile nuclei presented changes similar to those of the cortical nerve-cells. In the spinal cord the changes were slight or absent in the cells of the anterior cornua at various levels. No degeneration of the tracts in the spinal cord could be found with Marchi's method in seven cases examined. The tangential fibres of the cerebral cortex in six cases studied after staining with osmic acid appeared to be almost normal, there being a slight diminution in the numbers of the finer medullated fibres only. The fact that the cells of the hypoglossal nuclei were not affected in any of the cases and the anterior corneal cells only in advanced cases showed that the disease was not uniform throughout the nervous system. Dr. Turner claimed that the changes in melancholia began in the afferent part of the nervous system, beginning in the sensory roots and posterior spinal ganglia of the spinal nerves, so that the cells within the spinal cord—for example, in Clarke's column—were deprived of their natural sensory stimuli. The same condition applied to the sensory pathway proceeding upwards to the cerebrum, the cells of the cuneate and gracile nuclei being affected and the sensory tracts to the brain thus damaged. Thus was explained also the general and partial anæsthesias of the surface of the body in advanced melancholia, as was pointed out long ago by Griesinger. Bevan Lewis regarded the essence of mental pain as "pent up activity" and stated that all grades of mental pain were dependent on over-action of the impressive (or afferent) and restricted action of the expressive (or efferent) region, but this view of over-action must be regarded as doubtful in face of the admitted frequency of anæsthesia in melancholia. Apparently, according to Bevan Lewis, the barrier was in the efferent region, whereas the above observations showed that any barrier which might exist, was on the afferent pathways. Moreover, the theory that melancholic states depended upon a slighter reduction in the highest nervous centres than, maniacal states did not satisfactorily meet the facts of the case, and although undoubtedly most mental affections began with depression, yet they were by no means less grave than maniacal conditions. In Dr. Turner's experience melancholia more frequently than any other class of mental disorders, with the exception of general paralysis, tended in comparatively short periods to pass into dementia, and this passage often showed no intervening phase of mania as they should expect if the assumption just referred to were correct.

Dr. SEYMOUR TUKE (London) read a paper on

The Modern Treatment of the Insane,

referring to the difficulties under which alienists laboured under the existing lunacy laws. He thought that legislators had framed the laws in question in a spirit mainly of suspicion towards physicians engaged in lunacy practice or interested in private asylums and licensed houses. The Lunacy Act of 1890 was, owing to its "too repressive" nature, evaded by many, and unregistered places for the accommodation of insane private patients thus continued to exist. Then a prevailing practice existed of diagnosing cases of insanity as neurasthenia, hysteria, and as "borderland" cases, and the borderland was regarded as so elastic that it was made to include cases of insanity which in his opinion should be sent to asylums.

In the discussion which followed Mr. J. STEWART (Clifton, Gloucestershire) said his own experience confirmed the observations of Dr. Tuke, and he felt it was regrettable that owing to the abuse of the law by a class of practitioners who were not alienists the latter should have in large measure come to share the blame.

PATHOLOGY AND BACTERIOLOGY.

THURSDAY, AUGUST 1ST.

Mr. ALEXANDER G. R. FOULERTON (London), in introducing a discussion on

The Pathology of Pneumococcic Infection,

said that the pathology of pneumococcic infection was concerned with a large number of cases of diseases which in their clinical aspect might have but little in common and in their morbid anatomy might vary as widely. The specific organism of this infection, the pneumococcus, micrococcus pneumoniæ, or diplococcus lanceolatus, belonged to the class of strict parasites so far as our present knowledge went. Further, it appeared as infecting man alone and had never yet been found as a parasite of the lower animals. It had been but rarely met with outside the human body, but Emmerich had succeeded in isolating it from the dust of the floor of a ward in which there were patients with pneumonia and Uffelman claimed to have isolated it from the air of a cellar. From what was known of its biology it was improbable that the pneumococcus as it was found as a parasite of man could maintain a separate existence as a saprophyte and away from a living host for any length of time. Micrococcus pneumoniæ was a fairly common parasite of the mucous membranes in man and not necessarily under pathogenic conditions. It was first discovered accidentally by Pasteur, Chamberland, and Roux on inoculating rabbits with the saliva of a child who had died from hydrophobia and at about the same time by Sternberg on inoculating some rabbits with healthy saliva, and both accounts of the organism were published almost simultaneously in 1881. Subsequent investigations had shown the frequency with which the organism existed in the mouths of healthy individuals, in whom Sternberg found it in 20 per cent. of all cases examined, and Netter in about 15 per cent. The organism was also found in the anterior nares, von Besser isolating it from the nasal secretion of 14 out of 57 individuals examined. Arnold Lawson, when investigating the bacteriology of the conjunctival sac in 200 healthy individuals found micrococcus pneumoniæ present in two, and in each in pure culture. The parasite had also been found on the mucous membrane of the vagina, but it was probably rarely present there since Doyen was the only one of the large number of those who had worked at the bacteriology of this canal who had isolated it from the vaginal secretion.
